

# PCI Express Clock Generator

## Features

- Four 100 MHz differential clocks
- 48 MHz clock
- Two 25 MHz clocks
- 27 MHz Reference Clock
- OE control per clock output
- Selectable drive strength per output
- Selectable, Triangle, and Lexmark profiles
- SMBus support with readback capabilities
- 3.3V power supply
- Packages are Pb free and ROHS compliant
- 28-pin TSSOP packages

## Serial Data Interface

To enhance the flexibility and function of the clock synthesizer, a two signal serial interface is provided. Through the Serial Data Interface, various device functions, such as individual clock output buffers, can be individually enabled or disabled. The registers associated with the Serial Data Interface initialize to their default setting upon power up, and therefore use of this interface is optional. Clock device register changes are normally made upon system initialization, if any are required. This is a RAM based technology which does not keep its value when power is off or during a power transition.

## Data Protocol

The clock driver serial protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write or read operation, the bytes must be accessed in sequential order from lowest to highest byte (most significant bit first) with the ability to stop after any complete byte has been transferred. For byte write and byte read operations, the system controller can access individually indexed bytes. The offset of the indexed byte is encoded in the command code, as described in *Table 2*.

The block write and block read protocol is outlined in *Table 3* while *Table 4* on page 4 outlines the corresponding byte write and byte read protocol. The slave receiver address is 11010010 (D2h) for write and 11010011(D3h) for read.

**Table 2. Command Code Definition**

**Crystal Recommendations**

The CY28517 requires a Parallel Resonance Crystal. Substituting a series resonance crystal causes the CY28517 to operate at the wrong frequency and violate the ppm specification. For most applications there is a 300 ppm frequency shift between series and parallel crystals due to incorrect loading.

**Table 5. Crystal Recommendations**

Frequency (Fund)	Cut	Load Cap	Eff Series Rest	Drive (Max)	Tolerance (Max)	Stability (Max)	Aging (Max)
27.00 MHz	Parallel	18 pF	30 Ohm	50 $\mu$ W	30 ppm	10 ppm	5 ppm/Yr

**Crystal Loading**

Crystal loading plays a critical role in achieving low ppm performance. To realize low ppm performance, the total capacitance of the crystal must be considered to calculate the appropriate capacitive loading (CL).

Figure 2 on page 7 shows a typical crystal configuration using the two trim capacitors. An important clarification for the following discussion is that the trim capacitors are in series with the crystal not parallel. It's a common misconception that load capacitors are in parallel with the crystal and must be approximately equal to the load capacitance of the crystal. This is not true.

**Calculating Load Capacitors**

In addition to the standard external trim capacitors, trace capacitance and pin capacitance must also be considered to correctly calculate crystal loading.

As mentioned previously, the capacitance on each side of the crystal is in series with the crystal. This means the total capacitance on each side of the crystal must be twice the specified crystal load capacitance (CL). While the capacitance on each side of the crystal is in series with the crystal, trim capacitors (Ce1,Ce2) must be calculated to provide equal capacitive loading on both sides.

Figure 2. Crystal Loading Example

Use the following formulas to calculate the trim capacitor values for Ce1 and Ce2.

**Load Capacitance (each side)**

$$C_e = 2 * CL - (C_s + C_i)$$

**Total Capacitance (as seen by the crystal)**

$$CL_e = \frac{1}{\left( \frac{1}{C_{e1} + C_{s1} + C_{i1}} + \frac{1}{C_{e2} + C_{s2} + C_{i2}} \right)}$$

- CL ..... Crystal load capacitance
- CLe ..... Actual loading seen by crystal using standard value trim capacitors
- Ce ..... External trim capacitors
- Cs ..... Stray capacitance (terraced)
- Ci ..... Internal capacitance

MSL	Moisture Sensitivity Level		1		

**Multiple Supplies:** The voltage on any input or IO pin cannot exceed the power pin during power up. Power supply sequencing is NOT required.

**Output Enable**

The Output Enable (OE\_100\_25) signal is active HIGH input used for clean stopping and starting the selected 100M and 25M outputs. To recognize as a valid assertion or deassertion, the signal is a debounced signal in that its state must remain unchanged during two consecutive rising edges of 25 MHz.

The assertion and deassertion of this signal is absolutely asynchronous.

**Output Enable Deassertion**

Upon deasserting the Output Enable pin (OE\_100\_25) all 100M/25M outputs are stopped after their next transition. The final state of all stopped 100M/25M signals is LOW.

**Output Enable Assertion**

All 100 MHz/25 MHz outputs that were stopped resumes normal operation in a glitch free manner. The maximum latency from the assertion to active outputs is between 2–6 clock periods of 100 MHz/25 MHz with all 100M/25M outputs resuming simultaneously.
