

MC34270 MC34271

Liquid Crystal Display and Backlight Integrated Controller

The MC34270 and MC34271 are low power dual switching voltage regulators, specifically designed for handheld and laptop applications, to provide several regulated output voltages using a minimum of external parts. Two uncommitted switching regulators feature a very low standby bias current of 5.0 μA , and an operating current of 7.0 mA capable of supplying output currents in excess of 200 mA.

Both devices have three additional features. The first is an ELD Output that can be used to drive a backlight or a liquid crystal display. The ELD output frequency is the clock divided by 256. The second feature allows four additional output bias voltages, in specific proportions to V_B , one of the switching regulated output voltages. It allows use of mixed logic circuitry and provides a voltage bias for N-Channel load control MOSFETs™. The third feature is an Enable input that allows a logic level signal to turn-"off" or turn-"on" both switching regulators.

Due to the low bias current specifications, these devices are ideally suited for battery powered computer, consumer, and industrial equipment where an extension of useful battery life is desirable.

MC34270 and MC34271 Features:

- Low Standby Bias Current of 5.0 μA
- Uncommitted Switching Regulators Allow Both Positive and Negative Supply Voltages
- Logic Enable Allows Microprocessor Control of All Outputs
- Synchronizable to External Clock
- Mode Commandable for ELD and LCD Interface
- Frequency Synchronizable
- Auxiliary Output Bias Voltages Enable Load Control via N-Channel FETs

MOSFET is a trademark of Motorola, Inc.

MAXIMUM RATINGS ($T_A = 25^\circ\text{C}$, unless otherwise noted.)

Rating	Symbol	Value	Unit

OPERATING DESCRIPTION

The MC34270 and MC34271 series are monolithic, fixed frequency power switching regulators specifically designed for dc to dc converter and battery powered applications. These devices operate as fixed frequency, voltage mode regulators containing all the active functions required to directly implement step-up, step-down and voltage inverting converters with a minimum number of external components. Potential markets include battery powered, handheld, automotive, computer, industrial and cost sensitive consumer products. A description of each section is given below with the representative block diagram shown in Figure 9.

Oscillator

The oscillator frequency is programmed by resistor R_T . The charge to discharge ratio is controlled to yield a 95% maximum duty cycle at the switch outputs. During the fall time of the internal sawtooth waveform, the oscillator generates an internal blanking pulse that holds the inverting input of the AND gates high, disabling the output switching MOSFETs. The internal sawtooth waveform has a nominal peak voltage of 3.3 V and a valley voltage of 1.7 V.

Pulse Width Modulators

Both pulse width modulators consist of a comparator with the oscillator ramp voltage applied to the noninverting input, while the error amplifier output is applied to the inverting input. A third input to the comparator has a 0.5 mA typical current source that can be used to implement soft start. Output switch conduction is initiated when the ramp waveform is discharged to the valley voltage. As the ramp voltage increases to a voltage that exceeds the error amplifier output, the latch resets, terminating output MOSFET conduction for the duration of the oscillator ramp. This PWM/latch combination prevents multiple output pulses during a given oscillator cycle.

Each PWM circuit is enabled by a logic input. When disabled, the entire block is turned off, drawing only leakage current from the power source. Shared circuits, like the

reference and oscillator, can be activated by either EN_1 or EN_2 .

Circuit #1 has an ELD output which may be used to drive an LCD or backlight. Its output frequency is the oscillator frequency divided by 1024.

Error Amplifiers and Reference

Each error amplifier is provided with access to both inverting and noninverting inputs, and the output. The Error Amplifiers' Common Mode Input Range is 0 to 2.5 V. The amplifiers have a minimum dc voltage gain of 60 dB. The 1.25 V reference has an accuracy of $\pm 4.0\%$ at room temperature.

External loop compensation is required for converter stability. A simple low-pass filter is formed by connecting a resistive divider from the output to the error amplifier inverting input, and a series resistor-capacitor from the error amplifier output also to the to the inverting input. The step down converter is easiest to compensate for stability. The step-up and voltage inverting configurations, when operated as continuous conduction boost or flyback converters, are more difficult to compensate, and may require a lower loop design bandwidth.

MOSFET Switch Outputs

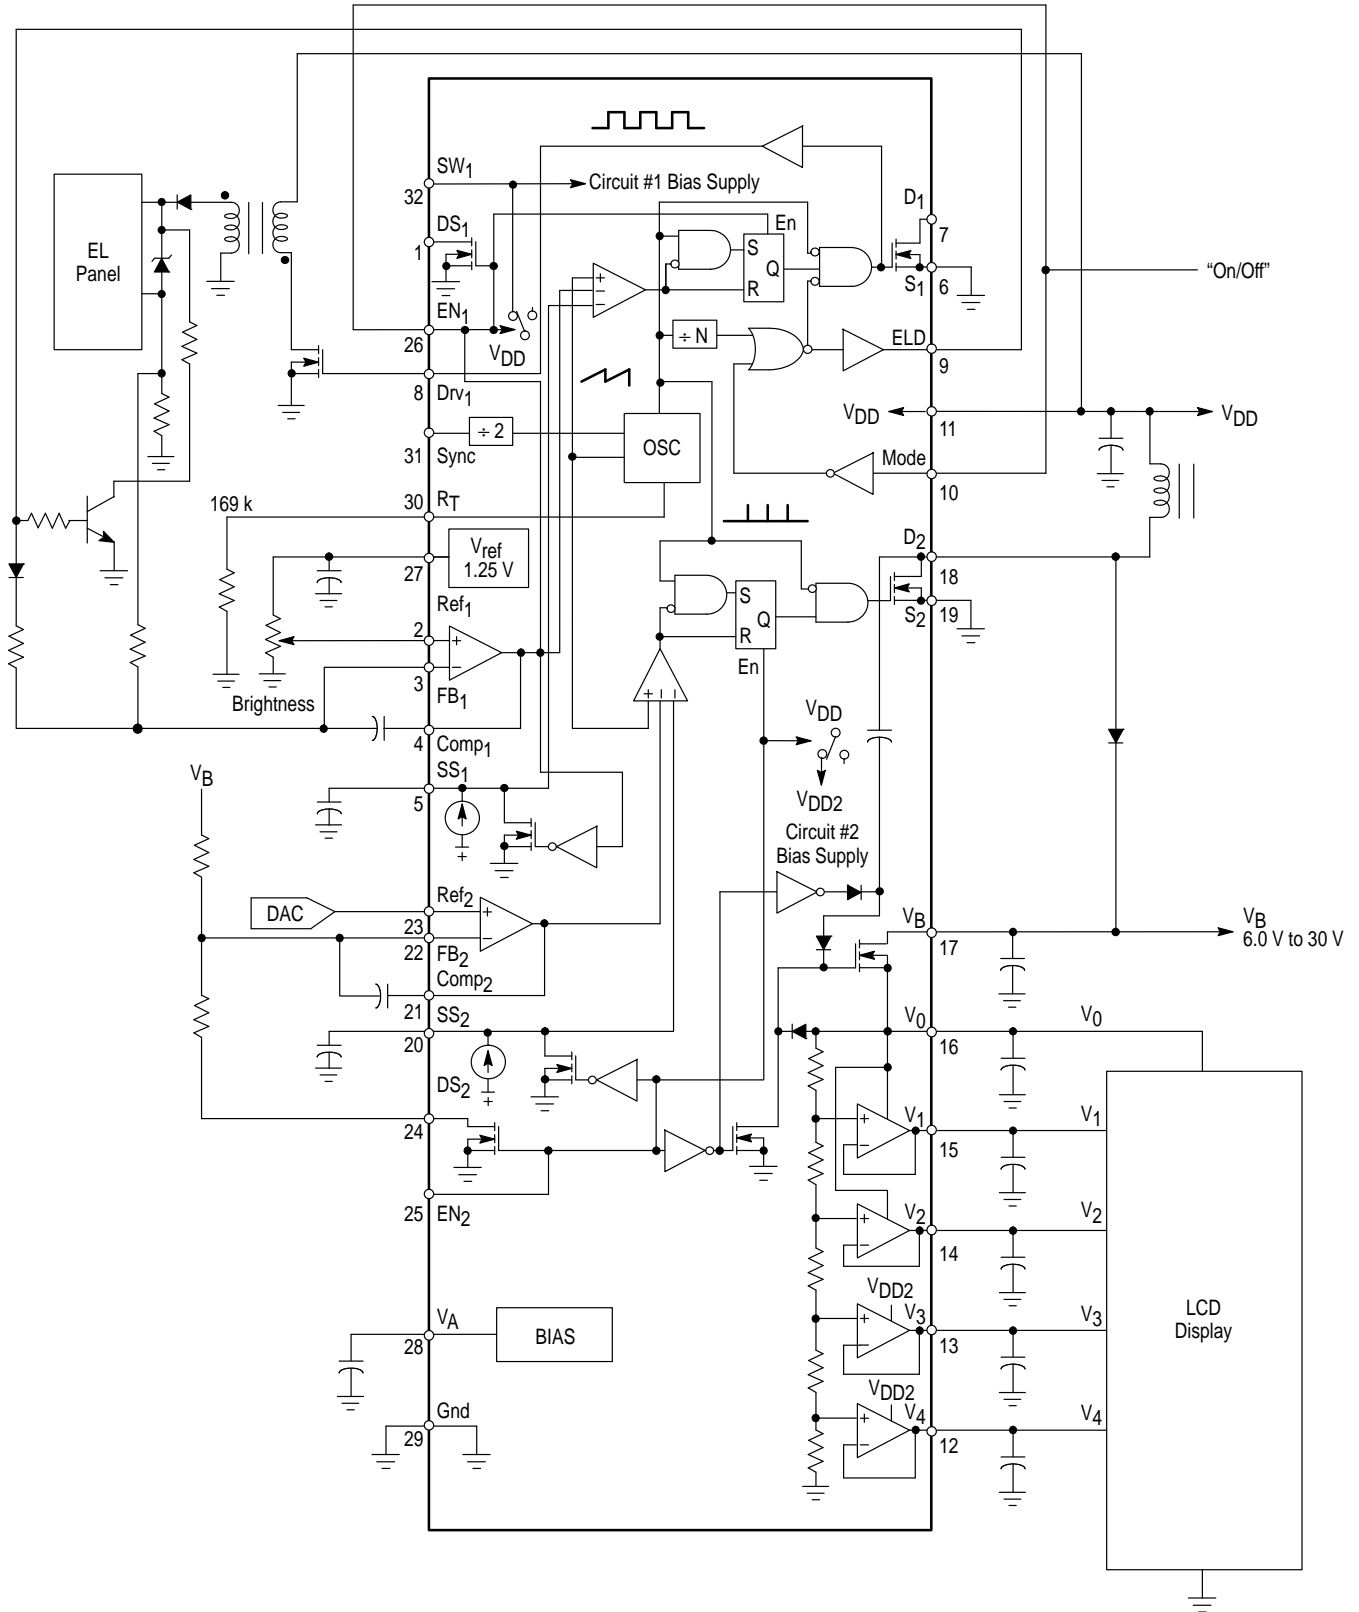

The output MOSFETs are designed to switch a maximum of 60 V, with a peak drain current capability of 500 mA. In circuit #1 an additional DRV_1 output is provided for interfacing with an external MOSFET. The gates of the MOSFETs are held low when the circuit is disabled.

Auxiliary Output Voltages

Output voltages V_0 through V_4 are provided for use as references or bias voltages. V_0 is the circuit #2 output voltage, when an internal FET switch is activated. The other auxiliary output voltages are proportional to V_B . The amplifiers for V_1 and V_2 are powered from V_0 , while the amplifiers for V_3 and V_4 are powered from V_{DD} .
