

- **Wide Operating Voltage Range: 2V to 16V**
- **Low Current Consumption: 2.7 mA Typically**
- **Chip Disable Input to Power Down the Integrated Circuit**
- **Low Power-down Quiescent Current**
- **Drives a Wide Range of Speaker Loads**
- **Output Power $P_o = 250 \text{ mW}$ at $R_L = 32\Omega$ (Speaker)**
- **Low Harmonic Distortion (0.5% Typically)**
- **Wide Gain Range: 0 dB to 46 dB**

- **Low Number of External Components**
- **Low Current Consumption**

The integrated circuit U4083B is a low-power audio amplifier for telephone loudspeakers. It has differential speaker outputs to maximize the output swing at low supply voltages. There is no need for coupler capacitors. The U4083B has an open-loop gain of 80 dB where the closed-loop gain is adjusted with two external resistors. A chip disable pin permits powering down and/or muting the input signal.

Low-power Audio Amplifier for Telephone Applications

U4083B

Rev. 4655C-CORD-03/06

2. Pin Configuration

Figure 2-1. Pinning SO8

Table 2-1. Pin Description

Pin	Symbol	Function
1	CD	Chip disable
2	FC2	Filtering, power supply rejection
3	FC1	Filtering, power supply rejection
4	V_i	Amplifier input
5	VO1	Amplifier output 1
6	V_s	Voltage supply
7	GND	Ground
8	VO2	Amplifier output 2

3. Functional Description Including External Circuitry

3.1 Pin 1: Chip Disable Digital Input (CD)

Pin 1 (chip disable) is used to power down the IC to conserve power or mute the IC or both.

Input impedance at Pin 1 is typically 90 k Ω

- Logic 0 < 0.8V IC enabled (normal operation)
- Logic 1 > 2V IC disabled

Figure 8-15 on page 12 shows the power supply current diagram. The change in differential gain from normal operation to muted operation (muting) is more than 70 dB.

Switching characteristics are as follows:

- Turn-on time $t_{on} = 12 \text{ ms to } 15 \text{ ms}$
- Turn-off time $t_{off} \leq 2 \mu\text{s}$

They are independent of C_1 , C_2 and V_S .

Voltages at Pins 2 and 3 are supplied from V_S and, therefore, do not change when the U4083B is disabled. The outputs, V_{O1} (Pin 5) and V_{O2} (Pin 8), turn to a high impedance condition by removing the signal from the speaker.

When signals are applied from an external source to the outputs (disabled), they must not exceed the range between the supply voltage, V_S , and ground.

3.2 Pins 2 and 3: Filtering, Power Supply Rejection

Power supply rejection is provided by capacitors C_1 and C_2 at Pin 3 and Pin 2, respectively. C_1 is dominant at high frequencies whereas C_2 is dominant at low frequencies (Figure 8-4 on page 8 to Figure 8-7 on page 9). The values of C_1 and C_2 depend on the conditions of each application. For example, a line-powered speakerphone (telephone amplifier) will require more filtering than a system powered by regulated power supply.

The amount of rejection is a function of the capacitors and the equivalent impedance at Pin 3 and Pin 2 (see electrical characteristic equivalent resistance, R).

Apart from filtering, capacitors C_1 and C_2 also influence the turn-on time of the circuit at power up, since the capacitors are charged up through the internal resistors (50 k Ω and 125 k Ω) as shown in the block diagram.

Figure 8-1 on page 7 shows the turn-on time versus C_2 at $V_S = 6V$, for two different C_1 values.

The turn-on time is 60% longer when $V_S = 3V$ and 20% shorter when $V_S = 9V$.

The turn-off time is less than 10 μs .

3.3 Pin 4: Amplifier Input V_i , Pin 5: Amplifier Output 1 V_{O1} , Pin 8: Amplifier Output 2 V_{O2}

There are two identical operational amplifiers. Amplifier 1 has an open-loop gain ≥ 80 dB at 100Hz (Figure 8-2 on page 7), whereas the closed-loop gain is set by external resistors, R_f and R_i (Figure 8-3 on page 8). The amplifier is unity gain stable, and has a unity gain frequency of approximately 1.5 MHz. A closed-loop gain of 46 dB is recommended for a frequency range of 300Hz to 3400Hz (voice band). Amplifier 2 is internally set to a gain of -1.0 dB (0 dB). The outputs of both amplifiers are capable of sourcing and sinking a peak current of 200 mA. Output voltage swing is between 0.4V and $V_S - 1.3V$ at maximum current (Figure 8-18 on page 13 and Figure 8-19 on page 13).

The output DC offset voltage between Pins 5 and 8 ($V_{O1} - V_{O2}$) is mainly a function of the feedback resistor, R_f , because the input offset voltages of the two amplifiers neutralize each other.

Bias current of Amplifier 1 which is constant with respect to V_S , flows out of Pin 4 (V_i) and through R_f , forcing V_{O1} to shift negative by an amount equal to $R_f I_{IB}$ and V_{O2} positive to an equal amount.

The output offset voltage specified in the electrical characteristics is measured with the feedback resistor ($R_f = 75$ k Ω) shown in the typical application circuit, Figure 8-20 on page 14. It takes into account the bias current as well as internal offset voltages of the amplifiers.

3.4 Pin 6: Supply and Power Dissipation

Power dissipation is shown in Figure 8-8 on page 9 to Figure 8-10 on page 10 for different loads. Distortion characteristics are given in Figure 8-11 on page 10 to Figure 8-13 on page 11.

$$P_{\text{totmax}} = \frac{T_{j\text{max}} - T_{\text{amb}}}{R_{\text{thJA}}}$$

where

$T_{j\text{max}}$ = Junction temperature = 140°C

T_{amb} = Ambient temperature

R_{thJA} = Thermal resistance, junction-ambient

Power dissipated within the IC in a given application is found from the following equation:

$$P_{\text{tot}} = (V_S \times I_S) + (I_{\text{RMS}} \times V_S) - (R_L \times I_{\text{RMS}}^2)$$

I_S is obtained from Figure 8-15 on page 12.

I_{RMS} is the RMS current at the load R_L .

The IC's operating range is defined by a peak operating load current of ± 200 mA (Figure 8-8 on page 9 to Figure 8-13 on page 11). It is further specified with respect to different loads (see Figure 8-14 on page 12). The left (ascending) portion of each of the three curves is defined by the power level at which 10% distortion occurs. The center flat portion of each curve is defined by the maximum output current capability of the integrated circuit. The right (descending) portion of each curve is defined by the maximum internal power dissipation of the IC at 25°C. At higher ambient temperatures, the maximum load power must be reduced according to the above mentioned equation.

3.5 Layout Considerations

Normally, a snubber is not needed at the output of the IC, unlike many other audio amplifiers. However, the PC-board layout, stray capacitances, and the manner in which the speaker wires are configured may dictate otherwise. Generally, the speaker wires should be twisted tightly, and should not be more than a few cm (or inches) in length.

4. Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Reference point pin 7, $T_{amb} = 25^{\circ}\text{C}$ unless otherwise specified.

Parameters	Symbol	Value	Unit
Supply voltage Pin 6	V_S	-1.0 to +18	V
Voltages Disabled Pins 1, 2, 3 and 4 Pins 5 and 8		-1.0 to ($V_S + 1.0$) -1.0 to ($V_S + 1.0$)	V V
Output current Pins 5 and 8		± 250	mA
Junction temperature	T_j	+140	$^{\circ}\text{C}$
Storage temperature range	T_{stg}	-55 to +150	$^{\circ}\text{C}$
