

TCM320AC46 GENERAL-PURPOSE AUDIO INTERFACE FOR DSP

SLWS001 – D4091, JUNE 1993

- **Single 5-V Operation**
- **Low Power Consumption:**
 Operating Mode . . . 55 mW Typ
 Standby Mode . . . 8 mW Typ
 Power-Down Mode . . . 3 mW Typ
- **Combined ADC, DAC, and Filters**
- **Extended Variable-Frequency Operation**
 Pass-Band up to 10 kHz
- **Electret Microphone Bias Reference**
 Voltage Available
- **Directly Drives a Piezo Speaker**
- **Compatible With All DSPs**
- **Selectable Between 8-Bit, μ -Law**
 Companded and 13-Bit Linear Conversion
- **Programmable Volume Control in Linear**
 Mode
- **Designed for Standard 2.048-MHz Master**
 Clock for U.S. Analog, U.S. Digital, CT2,
 Battery-Powered Telephones

description

The general-purpose audio interface for digital signal processors (DSPs) is designed to perform the transmit encoding (A/D conversion) and receive decoding (D/A conversion) together with transmit and receive filtering for voice-band audio systems. In particular, cellular telephone systems are targeted; however, this integrated circuit can function in several systems, including digital audio, multimedia telecommunications, noise cancellation, and other data acquisition.

The converted data is available in two formats. The formats are pin selectable between companded and linear. When the device is in the companded mode, data is transmitted and received in eight-bit words. When the linear mode is selected, 13 bits of data are sent and received, padded with trailing zeros or volume control bits to provide a 16-bit word.

The transmit section is designed to directly interface with an electret microphone element. A reference voltage equal to $V_{CC}/2$, called VMID, is used to develop the midlevel virtual ground for all the amplifier circuits and the microphone bias circuit. A reference voltage called MICBIAS can be used to supply bias current for the microphone. The microphone input signal (MICIN) is buffered and amplified with provision for setting the amplifier gain to accommodate a range of signal input levels. The amplified signal is passed through antialiasing and band-pass filters. The filtered signal is then input to a compressing analog-to-digital converter (COADC) if companded mode is selected; otherwise, the analog-to-digital converter performs a linear conversion.

Caution. These devices have limited built-in protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

TCM320AC46 GENERAL-PURPOSE AUDIO INTERFACE FOR DSP

SLWS001 – D4091, JUNE 1993

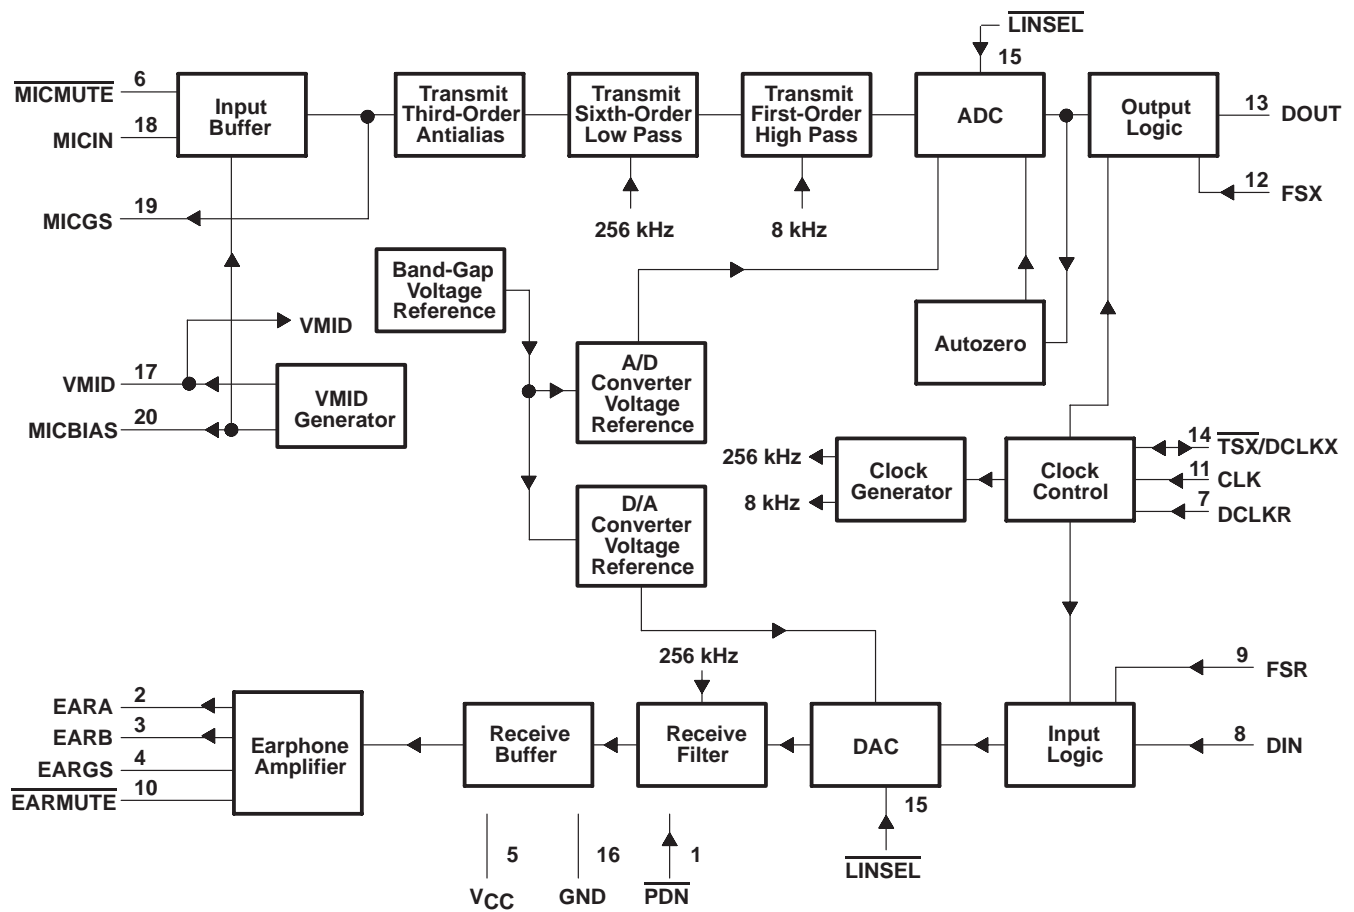

description (continued)

The receive section takes a frame of serial data on DIN and converts it to analog through an expanding digital-to-analog converter (EXDAC) if the companded mode is selected; otherwise, a linear conversion is performed. The analog signal then passes through switched-capacitor filters, which provide out-of-band rejection, $(\sin x)/x$ correction functions, and smoothing. The filtered signal is sent to the earphone amplifier. The earphone amplifier has a differential output with adjustable gain that is designed to minimize static power dissipation.

A single on-chip, high-precision band-gap circuit generates all voltage references, eliminating the need for external reference voltages.

The TCM320AC46 device is characterized for operation from 0°C to 70°C.

functional block diagram

TCM320AC46 GENERAL-PURPOSE AUDIO INTERFACE FOR DSP

SLWS001 – D4091, JUNE 1993

Terminal Functions

PIN NAME	NO.	I/O	DESCRIPTION
CLK	11	I	In the fixed-data-rate mode, CLK is the master clock input as well as the transmit and receive data clock input. In the variable-data-rate mode, CLK serves only as the master clock input.
DCLKR	7	I	Selects fixed- or variable-data-rate operation. When DCLKR is connected to V _{CC} , the device operates in the fixed-data-rate mode. When DCLKR is not connected to V _{CC} , the device operates in the variable-data-rate mode and DCLKR becomes the receive data clock.
DIN	8	I	Receive data input. Input data is clocked in on consecutive negative transitions of the receive data clock, which is CLK for a fixed data rate and DCLKR for a variable data rate.
DOUT	13	O	Transmit data output. Transmit data is clocked out on consecutive positive transitions of the transmit data clock, which is CLK for a fixed data rate and DCLKX for a variable data rate.
EARA	2	O	Earphone output. EARA forms a differential drive when used with the EARB signal.
EARB	3	O	Earphone output. EARB forms a differential drive when used with the EARA signal.
EARGS	4	I	Earphone gain set input of feedback signal for the earphone output. The ratio of an external potential divider network connected across EARA and EARB adjusts the power amplifier gain. Maximum gain occurs when EARGS is connected to EARB, and minimum gain occurs when EARGS is connected to EARA. Earphone frequency response correction is performed using an external RC filter.
EARMUTE	10	I	Earphone output mute control signal. When EARMUTE is low, the output amplifier is disabled and no audio is sent to the earphone.
FSR	9	I	Frame synchronization clock input for receive channel. In the variable-data-rate mode, FSR must remain high for the duration of the time slot. The receive channel enters the standby state when FSR is TTL low for five frames or longer. The device enters a production test-mode condition when either FSR or FSX is held high for five frames or longer.
FSX	12	I	Frame synchronization clock input for transmit channel. FSX operates independently of, but in an analogous manner to, FSR. The transmit channel enters the standby state when FSX is low for five frames or longer. The device enters a production test-mode condition when either FSX or FSR is held high for five frames or longer.
GND	16		Ground return for all internal analog and digital circuits
LINSEL	15	I	Linear selection input. When low, LINSEL selects linear coding/decoding. When high, LINSEL selects companded coding/decoding. The companded mode is μ -law.
MICBIAS	20	O	Bias voltage equal to VMID for the electret microphone
MICGS	19	O	Output of the internal microphone amplifier. MICGS used as the feedback to set the microphone amplifier gain. If sidetone is required, it is accomplished by connecting a series network between MICGS and EARGS.
MICIN	18	I	Electret microphone input to the internal microphone amplifier
MICMUTE	6	I	Microphone input mute control signal. When MICMUTE is active (low), the input amplifier is disabled, the microphone current is switched off, and zero code is transmitted.
PDN	1	I	Power-down input. When low, the device powers down to reduce power consumption.
TSX/DCLKX	14	I/O	Transmit time slot strobe (active-low output) or data clock (input) for the transmit channel. In the fixed-data-rate mode, this is an open-drain output that pulls to ground and is used as an enable signal for a 3-state buffer. In the variable-data-rate mode, DCLKX becomes the transmit data clock input.
V _{CC}	5		5-V supply voltage for all internal analog and digital circuits
VMID	17	O	V _{CC} /2 bias voltage reference. An external, low-leakage, high-frequency 1- μ F capacitor should be connected to VMID for filtering.

TCM320AC46

GENERAL-PURPOSE AUDIO INTERFACE FOR DSP

SLWS001 – D4091, JUNE 1993

general information

system reliability features

The device should be powered up and initialized as follows:

1. GND is applied.
2. V_{CC} is applied.
3. All clocks are connected.
4. TTL high is applied to \overline{PDN} .
5. FSX and/or FSR synchronization pulses are applied.

Even though the device is heavily protected against latch-up, it is still possible to cause it to latch-up under certain improper power conditions where excess current is forced into or out of one or more terminals. To assure that latch-up will not occur, it is good design practice to put a reverse-biased Schottky diode between V_{CC} (power supply) and GND.

On the transmit channel, digital outputs DOUT and \overline{TSX} are held in the high-impedance state for approximately four frames (500 μ s) after power up or application of V_{CC} . After this delay, DOUT, \overline{TSX} , and signaling are functional and occur in the proper time slot. The analog circuits on the transmit side require approximately 60 ms to reach their equilibrium value due to the autozero circuit settling time. To further enhance system integrity, DOUT and \overline{TSX} are placed in the high-impedance state after an interruption of CLK.

power-down and standby operations

To minimize power consumption, a power-down mode and three standby modes are provided.

For power down, an external low signal is applied to \overline{PDN} . In the absence of a signal, \overline{PDN} is internally pulled up to a high logic level and the device remains active. In the power-down mode, the average power consumption is reduced to 3 mW.

The standby modes give the user the options of putting the entire device on standby, putting only the transmit channel on standby, or putting only the receive channel on standby. To place the entire device on standby, both FSX and FSR are held low. For transmit-only operation, FSX is pulsed and FSR is held low. For receive-only operation, FSR is pulsed and FSX is held low. In the standby mode with both transmit and receive on standby, power consumption is reduced to 8 mW. See Table 1 for power-down and standby procedures.

Table 1. Power-Down and Standby Procedures

DEVICE STATUS	PROCEDURE	TYPICAL POWER CONSUMPTION	DIGITAL OUTPUT STATUS
Power on	$\overline{\text{PDN}}$ = high, FSX = pulses, FSR = pulses	55 mW	Digital outputs active but not loaded
Power down	$\overline{\text{PDN}}$ = low, FSX/FSR = X/X	3 mW	$\overline{\text{TSX}}$ and DOUT in the high-impedance state
Entire device on standby	FSX = low, FSR = low, $\overline{\text{PDN}}$ = high	8 mW	$\overline{\text{TSX}}$ and DOUT in the high-impedance state
Only transmit on standby	FSX = low, FSR = pulses, $\overline{\text{PDN}}$ = high	20 mW	$\overline{\text{TSX}}$ and DOUT in the high-impedance state within 5 frames
Only receive on standby	FSR = low, FSX = pulses, $\overline{\text{PDN}}$ = high	20 mW	Digital outputs active but not loaded

fixed-data-rate timing

Fixed-data-rate timing is selected by connecting $\overline{\text{DCLKR}}$ to V_{CC} . It uses the master clock (CLK), frame synchronization clocks (FSX and FSR), and the $\overline{\text{TSX}}$ output. FSX and FSR are inputs that set the sampling frequency. Data is transmitted on DOUT on the positive transitions of CLK following the rising edge of FSX. Data is received on DIN on the falling edges of CLK following FSR. A D/A conversion is performed on the received digital word, and the resulting analog sample is held on an internal sample-and-hold capacitor until transferred to the receive filter. The data word is eight bits long in the companded mode and sixteen bits long in the linear mode.

variable-data-rate timing

Variable-data-rate timing is selected by connecting $\overline{\text{DCLKR}}$ to the receive data clock. In this mode, the master clock (CLK) controls the switched-capacitor filters, while data transfer into DIN and out of DOUT is controlled by $\overline{\text{DCLKR}}$ and $\overline{\text{DCLKX}}$, respectively. This allows the data to be transferred into and out of the device at any rate up to the frequency of the master clock. $\overline{\text{DCLKR}}$ and $\overline{\text{DCLKX}}$ must be synchronous with CLK.

While the FSX input is high, data is transmitted from DOUT on consecutive positive transitions of $\overline{\text{DCLKX}}$. Similarly, while the FSR input is high, the data word is received at DIN on consecutive negative transitions of $\overline{\text{DCLKR}}$. The transmitted data word at DOUT is repeated in all remaining time slots in the frame as long as $\overline{\text{DCLKX}}$ is pulsed and FSX is held high. This feature, which allows the data word to be transmitted more than once per frame, is available only with variable-data-rate timing.

asynchronous operations

In order to avoid crosstalk problems associated with special interrupt circuits, the design includes separate converters, filters, and voltage references on the transmit and receive sides to allow completely independent operation of the two channels. In either timing mode, the master clock, data clock, and time slot strobe must be synchronized at the beginning of each frame.

precision voltage references

A precision band-gap reference voltage is generated internally and is used to supply all the references required for operation of both the transmit and receive channels. The gain in each channel is trimmed during the manufacturing process. This process ensures very accurate, stable gain performance over variations in supply voltage and device temperature.

TCM320AC46 GENERAL-PURPOSE AUDIO INTERFACE FOR DSP

SLWS001 – D4091, JUNE 1993

conversion laws

The TCM320AC46 provides μ -law companding operation. The linear mode utilizes a 13-bit 2s complement format.

transmit operation

microphone input

The microphone input amplifier is designed to simplify interface to electret-type microphone elements as shown in Figure 1. The VMID buffer circuit provides a voltage (MICBIAS) equal to $V_{CC}/2$ as a reference for the microphone amplifier and a bias voltage to the electret microphone. The microphone amplifier output (MICGS) is used in conjunction with a feedback network to the amplifier inverting input (MICIN) to set the amplifier gain. VMID is brought out to provide a place to filter the VMID voltage.

microphone mute function

The $\overline{\text{MICMUTE}}$ input disables the microphone amplifier and attenuates the signal on the MICGS output to a level that is 80 dB or more down from the signal on the MICIN input. $\overline{\text{MICMUTE}}$ also causes the digital circuitry to transmit all zero code on DOUT.

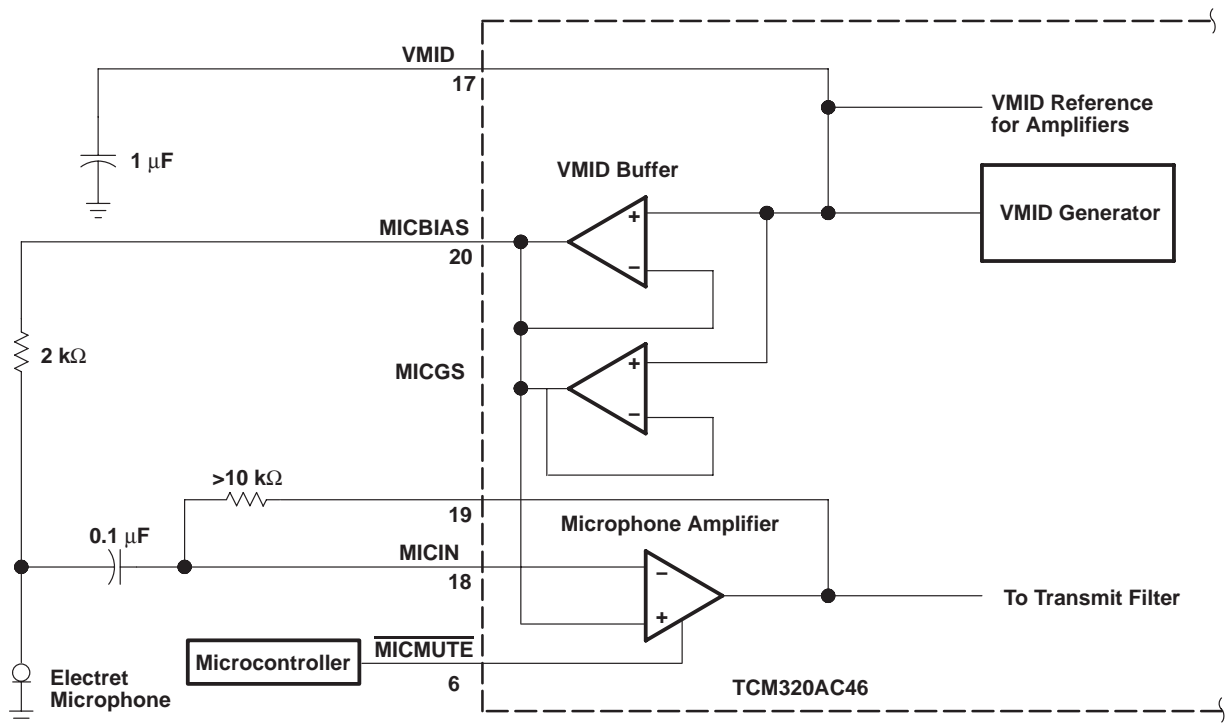

Figure 1. Typical Microphone Interface

transmit filter

A low-pass antialiasing section is included on the device. This section provides 35-dB attenuation at the sampling frequency. No external components are required to provide the necessary antialiasing function for the switched-capacitor section of the transmit filter.

encoding

The encoder internally samples the output of the transmit filter and holds each sample on an internal sample-and-hold capacitor. The encoder performs an analog-to-digital conversion on a switched-capacitor array. Digital data representing the sample is transmitted on the first eight or 16 data clock cycles of the next frame.

The autozero circuit corrects for dc offset on the input signal to the encoder using the sign-bit averaging technique. The sign bit from the encoder output is long-term averaged and subtracted from the input to the encoder.

data word structure

The data word is eight bits long in the companded mode. All eight bits represent one audio data sample. The sign bit is the first bit transmitted.

The data word is 16 bits long in the linear mode. The first 13 bits comprise the audio data sample, and the last three bits are volume control in the receive direction (DIN) and zeros in the transmit direction (DOUT). The sign bit is transmitted first.

receive operation

decoding

In the companded mode, the serial data word is received at DIN on the first eight clock cycles in fixed-data rate and the last eight clock cycles in variable-data rate. The serial data word is received at DIN on the first 13 clock cycles in the linear mode. Digital-to-analog conversion is performed, and the corresponding analog sample is held on an internal sample-and-hold capacitor. This sample is transferred to the receive filter.

receive filter

The receive section of the filter provides pass-band flatness. The filter contains the required compensation for the $(\sin x)/x$ response of such decoders.

receive buffer

The receive buffer contains the volume control.

earphone amplifier

The earphone amplifier has a balanced output to allow maximum flexibility in output configuration. The output amplifier is designed to directly drive a piezo earphone in the differential configuration without any additional external components. The output can also be used to drive a single-ended load with the output signal voltage centered around $V_{CC}/2$.

The receive-channel output level can be adjusted between specified limits by connecting an external resistor network to EARGS.

receive data format

Eight bits of data are received in the companded mode and are valid. The sign bit is the first bit received (see Table 2).

Sixteen bits of data are received in the linear mode. The first 13 bits are the D/A code, and the remaining three bits form the volume control word (see Table 2). The volume control function is actually an attenuation control where the first bit received is the most significant. The maximum volume occurs when all three volume control bits are zero. Eight levels of attenuation are selectable in 3-dB steps, giving a maximum attenuation of 21 dB, when all bits are 1s. The volume control bits are not latched into the device and must be present in each received data word.

SLWS001 – D4091, JUNE 1993

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)†

Supply voltage range, V_{CC} (see Note 1)	–0.3 V to 7 V
Output voltage range at DOUT, V_O	–0.3 V to 7 V
Input voltage range at DIN, V_I	–0.3 V to 7 V
Continuous total dissipation	See Dissipation Rating Table
Operating free-air temperature range	0°C to 70°C
Storage temperature range	–65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: Voltage value is with respect to GND.

DISSIPATION RATING TABLE

PACKAGE	$T_A \leq 25^\circ\text{C}$	DERATING FACTOR	$T_A = 70^\circ\text{C}$
	POWER RATING	ABOVE $T_A = 25^\circ\text{C}$	POWER RATING
DW	1025 mW	8.2 mW/°C	656 mW
N	1150 mW	9.2 mW/°C	736 mW

recommended operating conditions (see Note 2)

	MIN	MAX	UNIT
Supply voltage, V_{CC} (see Note 3)	4.5	5.5	V
High-level input voltage, V_{IH}	2.2		V
Low-level input voltage, V_{IL}		0.8	V
Load resistance between EARA and EARB, R_L (see Note 4)	50		Ω
Load capacitance between EARA and EARB, C_L (see Note 4)		113	nF
Operating free-air temperature, T_A	0	70	°C

NOTES: 2. To avoid possible damage to these CMOS devices and resulting reliability problems, the following sequence should be followed when applying power:

1. Connect to GND.
2. Connect V_{CC} .
3. Connect the input signals.

When removing power, follow the preceding steps in reverse order.

3. Voltages at analog inputs and outputs and V_{CC} are with respect to GND.
4. R_L and C_L should not be applied simultaneously.

electrical characteristics over recommended operating free-air temperature range (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	MAX	UNIT
Receive noise	DIN = 00000000(linear)		-60	dB
Receive signal-to-distortion ratio with sine-wave input	DIN to EARA and EARB at 0 dBm_0 to -6 dBm_0		48	dB
	DIN to EARA and EARB at -6 dBm_0 to -12 dBm_0		42	
	DIN to EARA and EARB at -13 dBm_0 to -18 dBm_0		38	
	DIN to EARA and EARB at -19 dBm_0 to -24 dBm_0		30	
	DIN to EARA and EARB at -25 dBm_0 to -45 dBm_0		14	

NOTES: 8. Transmit noise, linear mode: $200\text{ }\mu\text{Vrms}$ is equivalent to -74 dB (referenced to device 0-dB level).

9. Receive output is measured differentially in the maximum gain configuration. To set the output amplifier for maximum gain, EARGS is connected to EARB and the output is taken between EARA and EARB. All output levels are $(\sin x)/x$ corrected.

10. Unless otherwise noted, the digital input is a word stream generated by passing a 0-dB sine wave at 1020 Hz through an ideal encoder where 0 dB is defined as the zero reference.

11. This reference-signal level is measured at the speaker output of the receive channel with the gain of the output speaker amplifier set to unity.

power supply rejection and crosstalk attenuation over recommended ranges of supply voltage and operating free-air temperature

PARAMETER	TEST CONDITIONS	MIN	TYP†	MAX	UNIT
Supply voltage rejection ratio, transmit channel	Idle channel, supply signal = 100 mVrms, f = 0 to 30 kHz (measured at DOUT)		-30		dB
Supply voltage rejection ratio, receive channel	Idle channel, supply signal = 100 mVrms, EARGS connected to EARB, f = 0 to 30 kHz (measured differentially between EARA and EARB)		-30		dB
Crosstalk attenuation, transmit-to-receive (differential)	MICIN = 0 dB, f = 1.02 kHz, unity transmit gain, EARGS connected to EARB, measured differentially between EARA and EARB	55			dB
Crosstalk attenuation, receive-to-transmit	DIN = 0 dBm0, f = 1.02 kHz, unity transmit gain, measured at DOUT	55			dB

† All typical values are at $V_{CC} = 5\text{ V}$, $T_A = 25^\circ\text{C}$.

clock timing requirements over recommended ranges of supply voltage and operating free-air temperature (see Figures 2, 3, 4, and 5)

	MIN	TYP†	MAX	UNIT
t_t Transition time, CLK and DCLK			10	ns
Duty cycle, CLK	45%	50%	55%	
Duty cycle, DCLK	45%	50%	55%	

† All typical values are at $V_{CC} = 5\text{ V}$, $T_A = 25^\circ\text{C}$.

transmit timing requirements over recommended ranges of supply voltage and operating free-air temperature, fixed-data-rate mode (see Figure 3)

	MIN	MAX	UNIT
$t_{su}(\text{FSX})$ Setup time, FSX	20	468	ns
$t_h(\text{FSX})$ Hold time, FSX	20	468	ns

receive timing requirements over recommended ranges of supply voltage and operating free-air temperature, fixed-data-rate mode (see Figure 2)

	MIN	MAX	UNIT
$t_{su}(\text{FSR})$ Setup time, FSR	20	468	ns
$t_h(\text{FSR})$ Hold time, FSR	20	468	ns
$t_{su}(\text{DIN})$ Setup time, DIN	20		ns
$t_h(\text{DIN})$ Hold time, DIN	20		ns

t_{pd5} From CLK bit n low to FSX inactive (high)	$R_{pullup} = 1.24 \text{ k}\Omega$	30		ns

propagation delay times over recommended ranges of operating conditions, variable-data-rate mode (see Figures 4 and 5)

	TEST CONDITIONS	MIN	MAX	UNIT
t_{pd6} FSX high to DOUT bit 1 valid	$C_L = 0$ to 10 pF		30	ns
t_{pd7} DCLKX high to DOUT valid, bits 2 to n	$C_L = 0$ to 10 pF		40	ns
t_{pd8} FSX low to DOUT bit n Hi-Z		20		ns

PARAMETER MEASUREMENT INFORMATION

All timing parameters are referenced to V_{IH} and V_{IL} . Bit 1 = MSB (most significant bit) and is clocked in first on DIN or clocked out first on DOUT. Bit n = LSB (least significant bit) and is clocked in last on DIN or is clocked out last on DOUT. N = 8 for the companded mode, and N = 16 for the linear mode.

NOTES: A. This window is allowed for FSR high.
B. This window is allowed for FSR low.
C. Transitions are measured at 50%.

Figure 2. Fixed-Data-Rate, Receive Side Timing Diagram

NOTES: A. This window is allowed for FSX high.
B. This window is allowed for FSX low ($t_h(FSX)$ max determined by data collision considerations).
C. Transitions are measured at 50%.

APPLICATION INFORMATION

output gain set design considerations (see Figure 6)

EARA and EARB are low-impedance complementary outputs. The voltages at the nodes are:

V_{O+} at EARA

V_{O-} at EARB

$V_{OD} = V_{O+} - V_{O-}$ (total differential response)

R1 and R2 are a gain-setting resistor network with the center tap connected to EARGS.

A value greater than 10 k Ω and less than 100 k Ω for R1 + R2 is recommended because of the following:

The parallel combination R1 + R2 and R_L sets the total loading. The total capacitance at EARGS and the parallel combination of R1 and R2 define a time constant that has to be minimized to avoid inaccuracies.

APPLICATION INFORMATION

V_A represents the maximum available digital mW output response ($V_A = 1.06 \text{ Vrms}$).

$$V_{OD} = A \times V_A$$

$$\text{where } A = \frac{1 + (R1/R2)}{4 + (R1/R2)}$$

Figure 6. Gain-Setting Configuration

higher clock frequencies and sample rates

The TCM320AC46 is designed to work with sample rates up to 24 kHz where the frequency of the frame sync determines the sampling frequency. However, there is a fundamental requirement to maintain the ratio of master clock frequency, f_{CLK} , to frame sync frequency, f_{FSR}/f_{FSX} . This ratio for the device is 2.048 MHz/8 kHz or 256 master clocks per frame sync. For example, to operate the TCM320AC46 at a sampling rate of f_{FSR} and f_{FSX} equal to 16 kHz, f_{CLK} must be 256 times 16 kHz, or 4.096 MHz. If the TCM320AC46 is operated above an 8-kHz sample rate, however, it is expected that the performance will be degraded.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
