MAX98396

20V Digital Input Class-DG Amplifier with I/V Sense and Brownout Prevention

General Description

The MAX98396 is a high-efficiency, mono Class-DG speaker amplifier with industry-leading quiescent power featuring I/V sense, brownout-prevention engine (BPE), and dynamic-headroom tracking (DHT). The IC enables ultrasound applications by providing support for sample rates up to 192kHz, a higher passband (for f_S > 50kHz), and a bypass path for the ultrasound signals through the amplifier so it is not attenuated by the audio processing. Precision output current and voltage monitoring (I/V sense) enables the host device to run speaker protection algorithms. Spread-spectrum modulation (SSM) and edge rate control minimize EMI and eliminate the need for the output filtering found in traditional Class-D devices.

To achieve industry-leading quiescent power, the Class-DG amplifier employs two supply rails VBAT (3V to 5.5V) and PVDD (3V to 20V) to supply the speaker amplifier. The Class-DG amplifier switches between the two supply rails depending on the input signal level and/or the supply headroom. The brownout-prevention engine in the device allows it to reduce its contribution to the overall system power consumption by either attenuating or limiting the amplifier output when the device supply drops below a set of programmable thresholds. Additionally, as the power supply voltage varies due to sudden transients and declining battery life, DHT automatically optimizes the headroom available to the Class-DG amplifier to maintain consistent distortion and listening levels.

The device provides a PCM interface for audio data and a standard I^2C interface for control data communication. The PCM interface supports audio playback using I^2S, left-justified, and TDM audio data formats. A unique clocking structure eliminates the need for an external master clock for PCM communication, which reduces pin count and simplifies board layout. Enabling thermal foldback automatically reduces the output power when the temperature exceeds a user specified threshold. This allows for uninterrupted music playback even at high ambient temperatures. Traditional thermal protection is also available in addition to robust overcurrent protection.

The device is available in a 0.4mm pitch, 35-bump wafer-level package (WLP). The device operates over the extended -40°C to +85°C temperature range.

Applications

• Mobile Speakers • Smart Speakers • Smart IoT • Tablets

• Notebook Computers • Soundbars

SMBus is a trademark of Intel Corp.

Benefits and Features

- Wide Input Supply Range (3.0V to 20V)
- Class-DG Operation Enables Industry-Leading Quiescent Power
  - 12.7mW at V_{PVDD} = 12V , V_{VBAT} = 3.8V
  - 18mW at V_{PVDD} = 19V, V_{VBAT} = 5.0V
- Ultra-Low Noise Floor
  - 15.5µV_{RMS} Output Noise
  - 118dB Dynamic Range
- Low Distortion
  - -82dB THD+N at 1W into 8Ω, f = 1kHz
  - -76dB THD+N at 1W into 8Ω, f = 6kHz
- Output Power at 1% THD+N:
  - 20W into 8Ω, V_{PVDD} = 19V
  - 19W into 4Ω, V_{PVDD} = 14V
- 60W Peak Output Power into 4Ω, V_{PVDD} = 19V
- Speaker Amplifier Efficiency:
  - 87% at 1W into 8Ω, V_{PVDD} = 12V, V_{VBAT} = 3.8V
  - 83% at 1W into 4Ω, V_{PVDD} = 12V, V_{VBAT} = 3.8V
  - 83% at 1W into 8Ω, V_{PVDD} = 19V, V_{VBAT} = 5.0V
  - 91% at 20W into 8Ω, V_{PVDD} = 19V, V_{VBAT} = 5.0V
- Class-D EMI Reduction Enables Filterless Operation
- Spread-Spectrum Modulation
- Switching-Edge Rate Control
- Integrated Speaker Current and Voltage Sense do not Require External Components
- Flexible Brownout-Prevention Engine
- I^2S/16-Channel TDM and I^2C Digital Interfaces
- Playback Support for 16-, 24-, and 32-Bit Data Words
- Playback and I/V Sense Support Sample Rates up to 192kHz
- Audio Processing Bypass Path
- Dynamic-Headroom Tracking Maintains a Consistent Listening Experience
- Extensive Click-and-Pop Suppression
- 35-Bump, WLP (0.4mm Pitch)

Ordering Information appears at end of data sheet.

Short-Circuit Duration Between OUTP, OUTN, and PGND or PVDD or VBAT ..... Continuous
Short Circuit Duration Between OUTP and OUTN ..... Continuous
Continuous Power Dissipation for Multilayer Board (T_A = +70°C, derate 21.58mW/°C above +70°C) ..... mW to 1.73mW
Junction Temperature ..... +150°C
Operating Temperature Range ..... -40°C to +85°C
Storage Temperature Range ..... -65°C to +150°C
Soldering Temperature (reflow) ..... +260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Information

35 WLP

Package Code	W352F3Z+1
Outline Number	21-100489
Land Pattern Number	Refer to *Application Note 1891*
Thermal Resistance, Single Layer Board:	
Junction-to-Ambient (θ_{JA})	46.33
Junction-to-Case Thermal Resistance (θ_{JC})	N/A
Thermal Resistance, Four Layer Board:	
Junction-to-Ambient (θ_{JA})	
Junction-to-Case Thermal Resistance (θ_{JC})	N/A

For the latest package outline information and land patterns (footprints), go to *www.maximintegrated.com/packages*. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to *www.maximintegrated.com/thermal-tutorial*.

Electrical Characteristics

Release from $\overline{RESET}$	$t_{I^2C\_READY}$	Time from $\overline{RESET}$ = 1 to I^2C communication available (software shutdown)			1.5	ms

Note 1: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to *www.maximintegrated.com/thermal-tutorial*.

Note 2: 100% production tested at T_A = +25°C. Specifications over temperature limits are guaranteed by design. Typical values are based on one sigma characterization data unless otherwise noted.

Note 3: Minimum and/or maximum limit is guaranteed by design and by statistical analysis of device characterization data. The specification is not guaranteed by production testing.

Note 4: Assumes device is fully programmed (SPK_EN = 1) and EN = 1 is the last I^2C write in the sequence.

Note 5: Digital filter performance is invariant over temperature and is production tested at T_A = +25ºC.

Note 6: Applies to all transitions in/out of full operation with noise gate enabled/disabled. Does not include state transitions due to fault conditions.

Typical Operating Characteristics

Pin Description

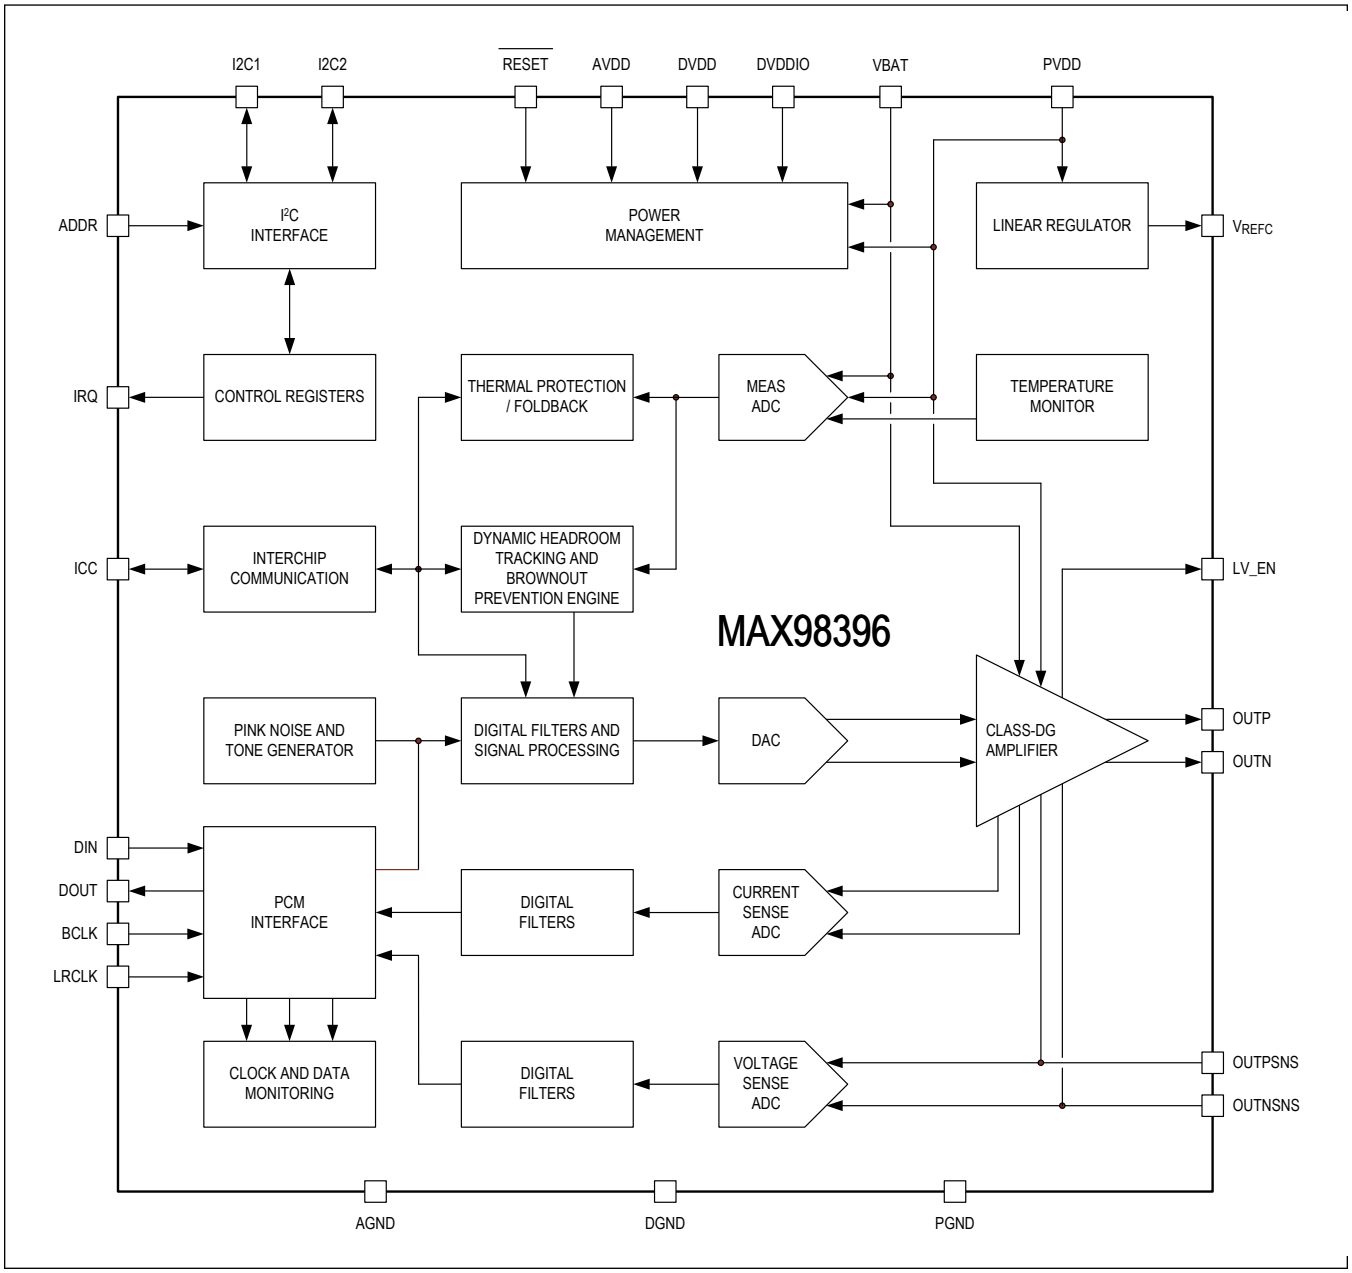
PIN	NAME	FUNCTION	REF SUPPLY	TYPE
B4	DVDD	Digital Core Power Supply. Bypass to GND with a 1µF capacitor.		Supply
B5	DVDDIO	Digital Core and Interface Power Supply. Bypass to DGND with a 0.1µF capacitor.		Supply
C5, C6	DGND	Digital Ground		Supply
A1, A2, E1, E2	PVDD	Speaker Amplifier Power Supply. Bypass each bump to PGND with a 0.1µF and 10µF capacitor placed as close as possible. Bypass the supply bus to PGND with a single 220µF bulk capacitor per device.		Supply
C1, C2, C3	PGND	Speaker Amplifier Ground		Supply
D4, E4	VBAT	Battery Power Supply. Bypass to PGND with a 0.1µF and 10µF capacitor placed as close as possible.		Supply

Pin Description (continued)

PIN	NAME	FUNCTION	REF SUPPLY	TYPE
A4	AVDD	Analog Power Supply. Bypass to GND with a 1µF capacitor placed as close as possible.		Supply
C4, D5, E5	AGND	Analog Ground. Connect to the common ground plane of the application.		Supply
E3	VREFC	Internal Bias. Bypass to GND with a 1µF capacitor.	PVDD	
A3	$\overline{\text{RESET}}$	Hardware Enable (Active Low). Resets all digital portions of the device and all registers to default PoR settings.	DVDDIO	Digital Input
D1, D2	OUTP	Positive Speaker Amplifier Output	PVDD	Analog Output
D3	OUTPSNS	Voltage Sense and Speaker Amplifier Feedback Positive Input. Connect as close as possible to the positive terminal of the loudspeaker. This pin must form a complete loop with OUTP and is not intended to be driven externally.	PVDD	Analog Output
B1, B2	OUTN	Negative Speaker Amplifier Output	PVDD	Analog Output
B3	OUTNSNS	Voltage Sense and Speaker Amplifier Feedback Negative Input. Connect as close as possible to the negative terminal of the loudspeaker. This pin must form a complete loop with OUTN and is not intended to be driven externally.	PVDD	Analog Output
B7	I2C1	I^2C-Compatible Serial-Data/Clock 1. This pin can be configured as either a SDA or SCL. Connect a 1.5kΩ pullup resistor to DVDDIO for full logic level swing.	DVDDIO	Digital I/O (Open drain)
A6	I2C2	I^2C-Compatible Serial-Data/Clock 2. This pin can be configured as either a SDA or SCL. Connect a 1.5kΩ pullup resistor to DVDDIO for full logic level swing.	DVDDIO	Digital I/O (Open Drain)
B6	ADDR	I^2C Address Select. Selects one of eight I^2C slave addresses in conjunction with I2C1 and I2C2 pins.	DVDDIO	Digital Input
A5	IRQ	Hardware Interrupt Output. Interrupt polarity and pin drive mode are configurable. Connect a 1.5kΩ pullup resistor to DVDDIO for full logic level swing in open drain mode.	DVDDIO	Digital Output
E7	BCLK	PCM Interface BCLK Input. Internally pulled down to DGND through R_{PD}.	DVDDIO	Digital Input
E6	LRCLK	PCM Interface Frame Clock Input/Output. LRCLK frequency matches the PCM interface sample rate. Internally pulled down to DGND through R_{PD}.	DVDDIO	Digital Input
D7	DIN	PCM Interface Data Input. Internally pulled down to DGND through R_{PD}.	DVDDIO	Digital Input
C7	DOUT	PCM Interface Data Output	DVDDIO	Digital Output
D6	LV_EN	Low Voltage Enable Output. This pin signals an external boost the active power supply used by the amplifier output stage. The pin is asserted when the amplifier uses VBAT as the supply for the output stage.	DVDDIO	Digital Ouput (Open Drain)
A7	ICC	Interchip Communication Data Bus. Optionally allows multiple devices to be grouped up to communicate with each other. Internally pulled down to DGND through R_{PD}.	DVDDIO	Digital I/O

Functional Diagrams

Detailed Block Diagram



Detailed Description

Device State Control

The device has three distinct power states: the hardware shutdown state, software shutdown state, and active state. When transitioning between states, the device always moves from the hardware shutdown state to the software shutdown state to the active state (or the reverse) based on the state transition requirements. Normal transitions between the software shutdown state and active state are reversible without waiting for an in-progress transition to be completed. State transitions due to fault conditions, supply removal, and reset conditions are not reversible and are always completed (once initiated) to protect the device.

Hardware Shutdown State

When the device is first powered up or after a hardware reset event, the device always initializes into the hardware shutdown state. In hardware shutdown, the device is configured to its lowest power state. Upon entering hardware shutdown, the device is globally placed into a reset condition. As a result, the I^2C control interface is disabled and all device registers are returned to their PoR states. When exiting hardware shutdown, the device initializes and then transitions into the software shutdown state. During this transition (as part of initialization), the OTP register trim settings are loaded. If the OTP load routine fails to complete successfully, an *OTP_FAIL_** interrupt is generated once the device reaches the software shutdown state.

When the hardware reset input ($\overline{RESET}$) is asserted low, the device enters (or remains in) hardware shutdown. The device is also placed into hardware shutdown anytime the AVDD, DVDD, or DVDDIO supplies drop below their respective UVLO thresholds. The device only exits hardware shutdown when the AVDD, DVDD, and DVDDIO supplies are all above their respective UVLO thresholds and the hardware reset input ($\overline{RESET}$) is asserted high. Once all of these conditions are met, the device automatically exits hardware shutdown and transitions into software shutdown.

Software Shutdown State

The device enters the software shutdown state after it transitions out of the hardware shutdown state and when exiting the active state. In the software shutdown state, all blocks are automatically disabled except for the I^2C control interface. In the software shutdown state, all device registers can be programmed without restriction and all programmed register states are retained.

The global enable bit (*EN*) is used to transition the device into and out of software shutdown. When global enable (*EN*) is set high, the device transitions to the active state and a power-up done (*PWRUP_DONE_**) interrupt is generated. When the device is in the active state and global enable (*EN*) is set low, the device transitions to the software shutdown state and a power-down done (*PWRDN_DONE_**) interrupt is generated. Additionally, the device is reset and enters software shutdown anytime the global enable bit (*RST*) is written with a 1.

By default, the device supply configuration is PVDD and VBAT pins being supplied with voltages and in this scenario, regardless of the state of the global enable bit, the device cannot transition from the software shutdown state to the active state until PVDD and VBAT are all above their UVLO thresholds. If PVDD or VBAT supplies drop below their UVLO levels while the device is in the active state, the device is forced back into the software shutdown state.

In systems where the VBAT supply is not available, the device is configured to operate with PVDD only by connecting the VBAT pin to the VREFC pin on the PCB and setting the NOVBAT bit to 1. In this scenario, regardless of the state of the global enable bit, the device cannot transition from the software shutdown state to the active state until PVDD is above its UVLO thresholds. If PVDD supply drops below its UVLO levels while the device is in the active state, the device is forced back into the software shutdown state.

While in the software shutdown state, the PVDD and VBAT (if applicable) supplies can be powered down safely.

Recovery from Software Shutdown due to Supply Faults

The device provides two forms of fault recovery in the event that either VBAT or PVDD drop below their UVLO thresholds while the device is in its active state. Based on the setting of the *VBAT_AUTORESTART_EN* and *PVDD_AUTORESTART_EN* bits, the individual supply fault recovery is either in manual mode or auto restart mode.

If the bit is set low, then the supply UVLO fault recovery is in manual mode. In manual mode, when the supply drops below its UVLO threshold, the device transitions into the software shutdown state (sets *EN* = 0) and generates the appropriate UVLO fault shutdown interrupt (*VBAT_UVLO_SHDN_** or *PVDD_UVLO_SHDN_** respectively). Even once the supply recovers (when voltage levels exceed the UVLO thresholds), the device remains in the software shutdown state until the global enable bit (*EN*) is set high by the host software.

If the bit is instead set high, then the supply UVLO fault recovery is in auto restart mode. In auto restart mode, when the supply drops below its UVLO threshold, the device is internally forced into software shutdown (*EN* state is preserved and remains high) and generates the appropriate UVLO fault shutdown interrupt (*VBAT_UVLO_SHDN_** or *PVDD_UVLO_SHDN_** respectively). Once the supply recovers (voltage levels exceed the UVLO thresholds), the device is no longer held in software shutdown and automatically restarts back into the active state (if all other conditions are met). These recovery modes do not apply when the AVDD, DVDD, or DVDDIO supplies cause a UVLO fault while the device is in the active state. If AVDD, DVDD, or DVDDIO drop below their UVLO thresholds, the device is reset and is placed into hardware shutdown.

Active State

The device always enters the active state through a transition from the software shutdown state. In the active state, all enabled device blocks are active and speaker amplifier playback is possible. In the active state, only dynamic register settings (or those restricted to disabled blocks) can be programmed safely.

The only non-fault state transitions to or from the active state are those initiated through the global enable bit (*EN*). All other transitions to or from the active state are the result of fault events, and can result in audible glitches if they occur during active playback.

Device Sequencing

Table 1 and Table 2 show the recommended typical device power-up and power-down sequences.

Table 1. Typical Power-Up Sequence

STEP	ACTION	DETAILED DESCRIPTION
1	Power-Up Core Supplies	Power the PVDD, VBAT, DVDD, DVDDIO, and AVDD supplies above their UVLO thresholds. If the VBAT pin is unavailable in the system, connect the VBAT pin to the VREFC pin.
2	Exit Hardware Shutdown State	Assert the hardware reset input ($\overline{RESET}$) to a logic high level. If $\overline{RESET}$ is tied to the DVDD/DVDDIO supply, this step is combined with step 1.
3	Enter Software Shutdown State	The device finishes the transition and enters the software shutdown state after the release from reset time ($t_{I^2C\_READY}$) elapses.
4	Program the Device Registers/Enable the External Clocks	The I^2C interface is active, and all registers can be freely configured. If the VBAT pin is unavailable in the system, set the NOVBAT bit to logic high. Start both external clocks before exiting the software shutdown state.
5	Exit Software Shutdown State	If volume ramping is disabled, the input audio data should be silent. Set the global enable to a logic high (*EN* = 1).
6	Enter the Active State	Device enters the active state after the turn-on time (t_{ON}) elapses.
7	Active State/Audio Playback	Dynamic bits (and those restricted to disabled blocks) can be programmed. The device is capable of audio playback in the active state.

Table 2. Typical Power-Down Sequence

STEP	ACTION	DETAILED DESCRIPTION
1	Exit the Active State	If volume ramping is disabled, the input audio data should be silent. Set the global enable bit to a logic low (*EN* = 0)
2	Enter Software Shutdown State	Device enters software shutdown state after the turn-off time (t_{OFF}) elapses.

Table 2. Typical Power-Down Sequence (continued)

STEP	ACTION	DETAILED DESCRIPTION
3	Reprogram Device Registers/Disable the External Clocks	The device is fully programmable, and can idle in the software shutdown state. To return to the active state, resume the power-up sequence from step 5.
4	Enter Hardware Shutdown State	For full hardware shutdown, disable the external clocks first. Assert the reset input ($\overline{RESET}$) to ground or power down DVDD/DVDDIO. The AVDD/PVDD/VBAT supplies (if applicable) can be disabled.

PCM Interface

The flexible PCM slave interface supports common audio playback sample rates from 16kHz to 192kHz and I/V sense ADC sample rates from 8kHz to 192kHz. The PCM interface also supports standard I²S, left-justified, and TDM data formats. The PCM interface is disabled and powered down when both the PCM data input (DIN) and PCM data output (DOUT) are disabled.

PCM Clock Configuration

The PCM slave interface requires the host to supply both BCLK and LRCLK. To configure the PCM interface clock inputs, the host must program both the device interface sample rate (*PCM_SR*) and BCLK to LRCLK (*PCM_BSEL*) ratio. The PCM interface sample rate must be configured to match the frequency of the frame clock (LRCLK) using the *PCM_SR* registers. The speaker path sample rate is also set by the *PCM_SR* setting. However, the I/V sense ADC path sample rate (*IVADC_SR)* can be set to the same rate or lower rate than the speaker path sample rate (*PCM_SR*) according to the restrictions in Table 3. When the I/V sense ADC path is set to a lower rate than the speaker amplifier path, the output data contains repeated samples.

Table 3. Sample Rate Selection for I/V Sense

N/A = Not Available N/S = Not Supported		I/V SENSE ADC SAMPLE RATE (kHz)											
		192	96	88.2	48	44.1	32	24	22.05	16	12	11.025	8
PCM Interface and Speaker Path Sample Rate (kHz)	192	1	2	N/S	4	N/S	6	8	N/S	12	16	N/S	24
	96	N/A	1	N/S	2	N/S	3	4	N/S	6	8	N/S	12
	88.2	N/A	N/A	1	N/S	2	N/S	N/S	4	N/S	N/S	8	N/S
	48	N/A	N/A	N/A	1	N/S	N/S	2	N/S	3	4	N/S	6
	44.1	N/A	N/A	N/A	N/A	1	N/S	N/S	2	N/S	N/S	4	N/S
	32	N/A	N/A	N/A	N/A	N/A	1	N/S	N/S	2	N/S	N/S	4
	24	N/A	N/A	N/A	N/A	N/A	N/A	1	N/S	N/S	2	N/S	3
	22.05	N/A	N/A	N/A	N/A	N/A	N/A	N/A	1	N/S	N/S	2	N/S
	16	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	1	N/S	N/S	2

The device supports a range of BCLK to LRCLK clock ratios (*PCM_BSEL*) ranging from 32 to 512. However, based on the selected PCM interface sample rate (LRCLK frequency), the configured clock ratio cannot result in a BLCK frequency that exceeds 24.576MHz.

PCM Data Format Configuration

The device supports the standard I²S, left-justified, and TDM data formats. The operating mode is configured using the *PCM_FORMAT* bit field.

I²S/Left-Justified Mode

I²S and left-justified formats support two channels that can be 16-, 24-, or 32-bits in length. The BCLK to LRCLK ratio (*PCM_BSEL*) must be configured to be twice the desired channel length. The audio data word size is configurable to 16-, 24-, or 32-bits in length (*PCM_CHANSZ*), but must be programmed to be less than or equal to the channel length. If

the resulting channel length exceeds the configured data word size then the data input LSBs are truncated and the data output LSBs are padded with either zero or Hi-Z data based on the *PCM_TX_EXTRA_HIZ* register bit setting.

Table 4. Supported I²S/Left-Justified Mode Configurations

CHANNELS	CHANNEL LENGTH	BCLK TO LRCLK RATIO (*PCM_BSEL*)	SUPPORTED DATA WORD SIZES (*PCM_CHANSZ*)
2	16	32	16
	24	48	16, 24
	32	64	16, 24, 32

With the default PCM settings, falling LRCLK indicates the left channel data (Channel 0) and the start of a new frame while rising LRCLK indicates the right channel data (Channel 1). In I²S mode, the MSB of the audio word is latched on the second active BCLK edge after an LRCLK transition. In left-justified mode, the MSB of the audio word is latched on the first active BCLK edge after an LRCLK transition.

The *PCM_BCLKEDGE* register bit selects either the rising or falling edge of BCLK as the active edge that is used for data capture (DIN) and data output (DOUT). The *PCM_CHANSEL* bit configures which LRCLK edge indicates the start of a new frame (Channel 0), and LRCLK transitions always align with the inactive BCLK edge. The data output is valid on the same active BCLK edge as the data input. The data output also transitions on the same edge as the data input.

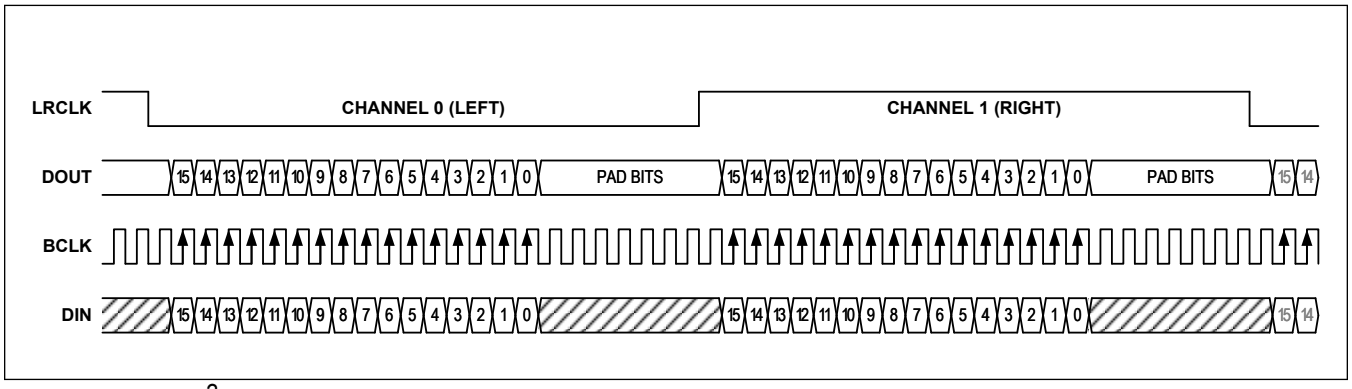


Figure 1. Standard I²S Mode

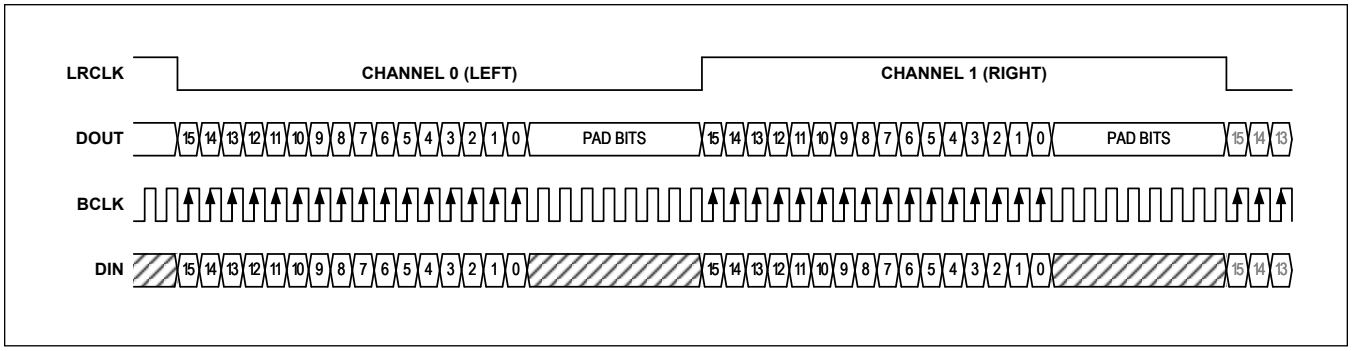

Figure 2. Left-Justified Mode

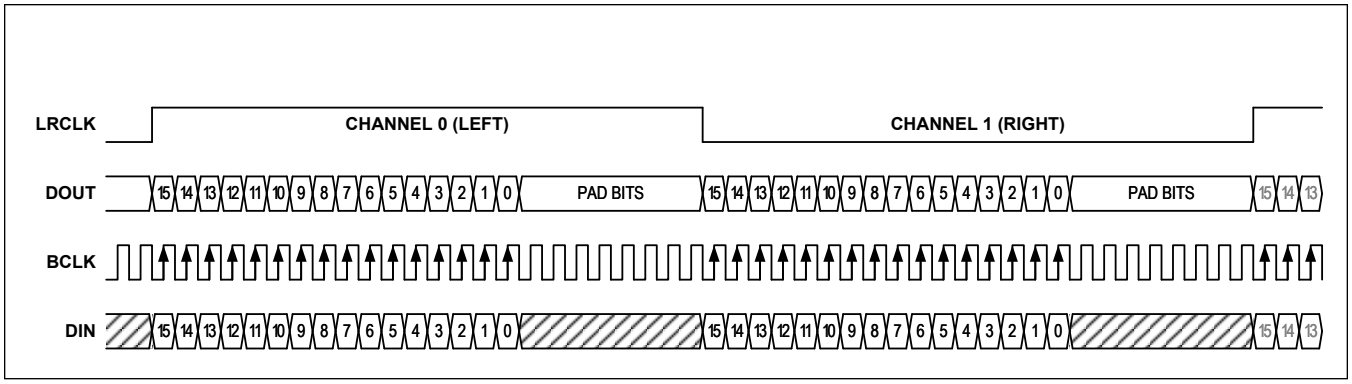

Figure 3. Left-Justified Mode (LRCLK Inverted)

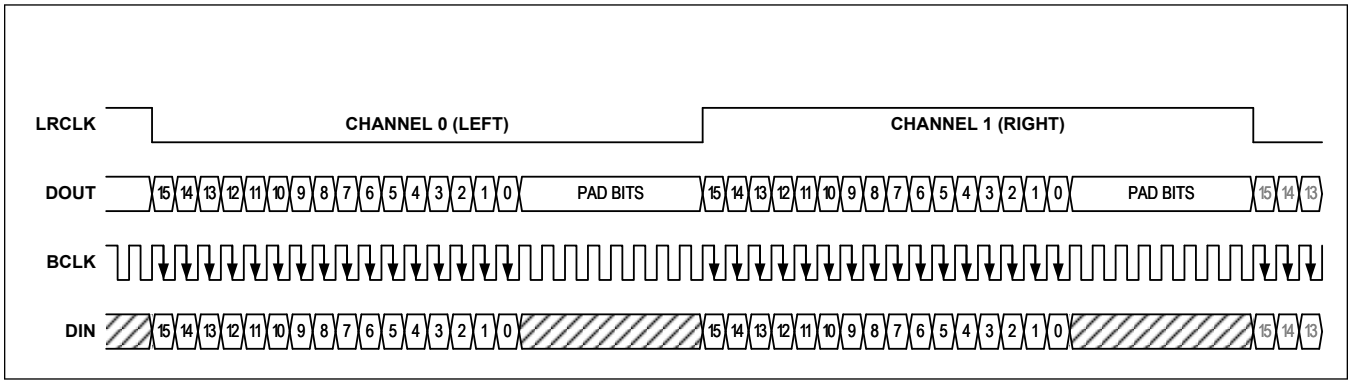

Figure 4. Left-Justified Mode (BCLK Inverted)

TDM Modes

The provided TDM modes support timing for up to 16 digital audio input channels (DIN), each containing 16-, 24-, or 32-bits of data. The digital audio output (DOUT) is structured into 8-bit slots, and the timing can support up to a maximum of 128 data output slots. The number of TDM input channels and output slots is determined by both the selected BCLK to LRCLK ratio (*PCM_BSEL*) and the selected data word and channel length (*PCM_CHANSZ*).

For a given valid configuration, the number of available data input channels per frame is calculated as follows:

Number of Available Data Input Channels = BCLK to LRCLK Ratio/Channel Length

For a given valid configuration, the number of available 8-bit data output slots per frame is calculated as follows:

Number of Available Data Output Slots = BCLK to LRCLK Ratio/8

Table 5 shows the supported TDM mode configurations for each combination of input data channels and output data slots. In some configurations, the maximum PCM interface and speaker amplifier playback sample rate is limited to less than 96kHz to avoid violating the BCLK frequency limit of 24.576MHz.

Table 5. Supported TDM Mode Configurations

INPUT DATA CHANNELS	OUTPUT DATA SLOTS	DATA WORD SIZES (PCM_DATA_WIDTH)	BCLK TO LRCLK RATIO (PCM_BSEL)	MAXIMUM SPEAKER PLAYBACK SAMPLE RATE (FLRCLK)
2	4	16	32	192kHz
	6	24	48	
	8	32	64	
3	15	32	125

With the default PCM interface settings in TDM mode, a rising frame clock (LRCLK) edge acts as the frame sync pulse and indicates the start of a new frame. The frame sync pulse width must be equal to at least one bit clock period. However, the falling edge can occur at any time as long as it does not violate the setup time of the next frame sync pulse rising edge. The *PCM_CHANSEL* bit can be used to invert the LRCLK edges (sync pulse) used to start a TDM frame.

In TDM mode, the MSB of the first audio word can be latched on the first (TDM Mode 0), second (TDM Mode 1), or third (TDM Mode 2) active BCLK edge after the sync pulse and is programmed by the *PCM_FORMAT* bits. Additionally, the *PCM_BCLKEDGE* register bit allows the BLCK edge (that is used for data capture and data output) to be programmed. The data output is valid on the same active BCLK edge as the data input. The data output also transitions on the same edge as the data input.

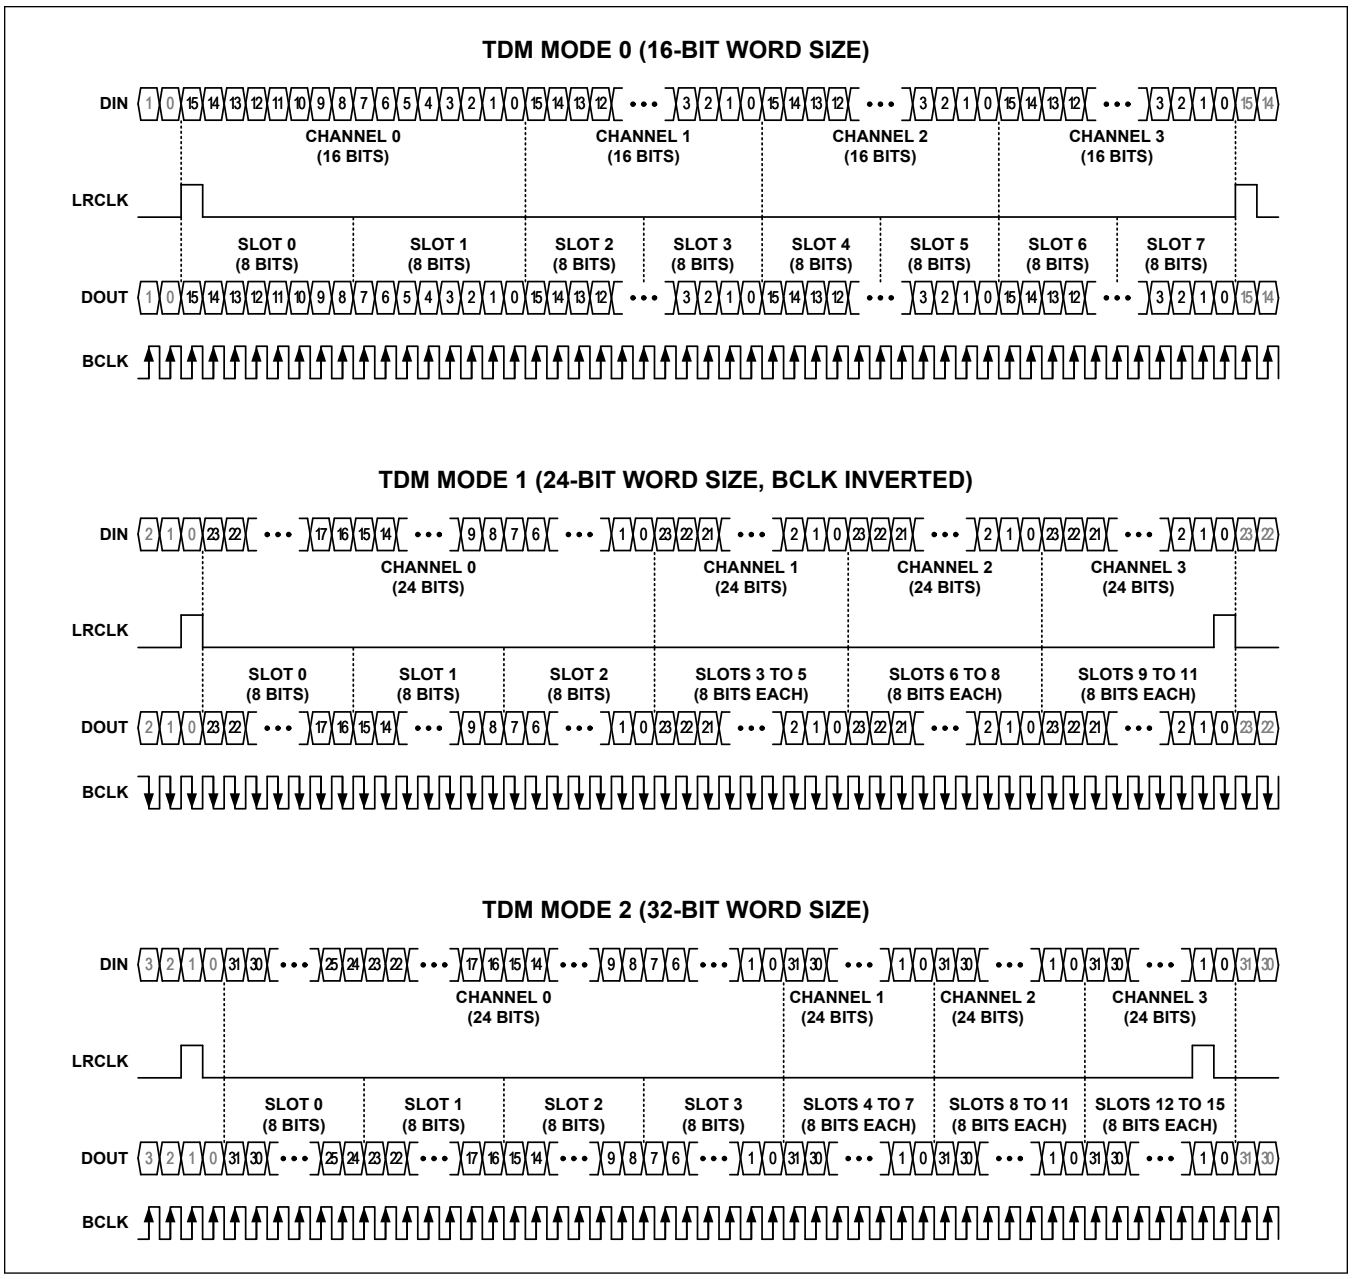

Figure 5. TDM Modes

PCM Data Path Configuration

The PCM interface data input (DIN) receives the source data for the speaker amplifier path and the speaker audio processing bypass path while the data output (DOUT) transmits the data from the I/V sense ADC path. In addition, the PCM data output can also transmit internal diagnostic data such as the speaker DSP monitor path, supply measurement ADC results, device status reporting, and the DHT attenuation level.

PCM Data Input

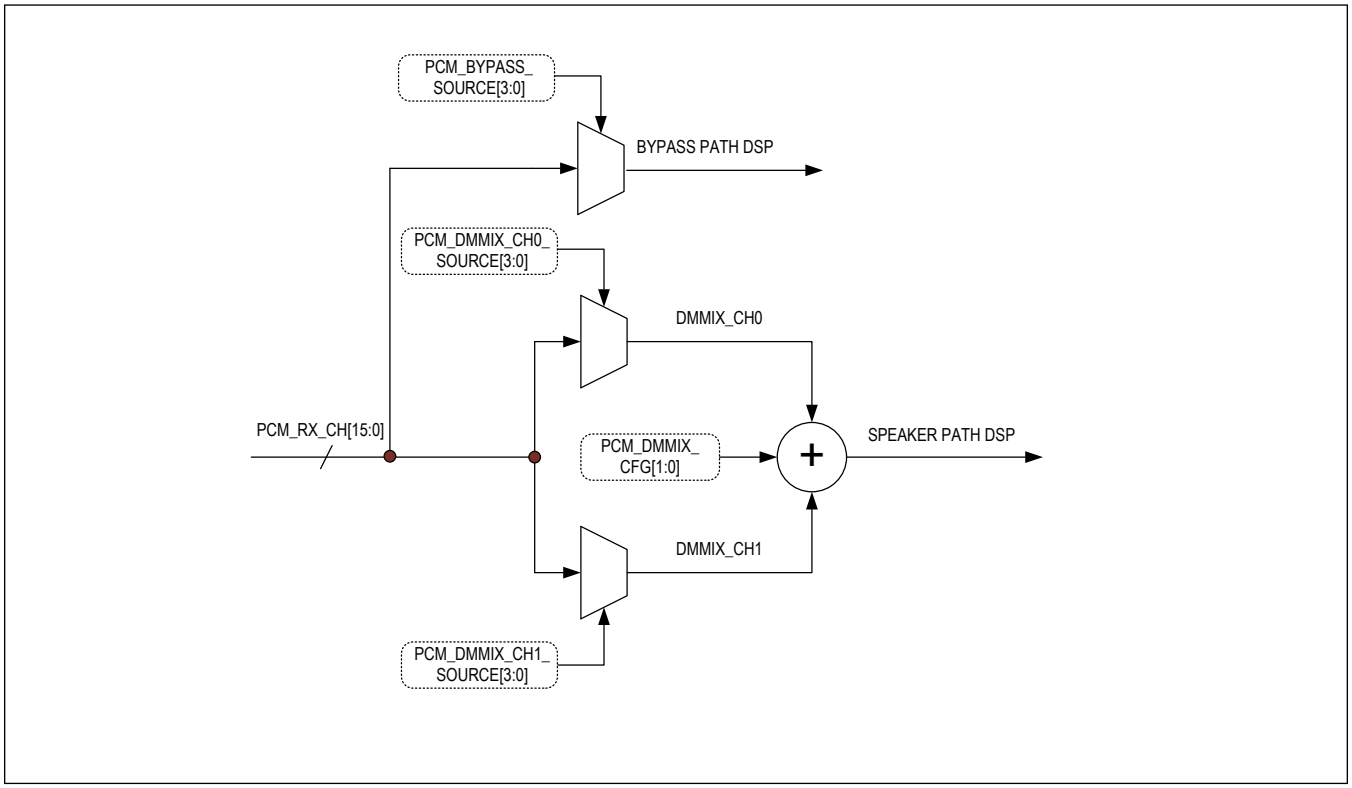

Figure 6. PCM Data Input

The PCM playback path is enabled with the *PCM_RX_EN* bit and can accept data from any valid input data channel. The device provides an input digital mono mixer that can route a single channel or mix two PCM input channels to create a mono input to the speaker playback path. The *PCM_DMMIX_CFG* bit is used to configure the mixer, while the *PCM_DMMIX_CH0_SOURCE* and *PCM_DMMIX_CH1_SOURCE* bits select which of the 16 PCM input channels are used as the input to the mono mixer. In I^2S and left-justified modes, only two input data channels are available while in TDM mode up to 16 channels of input data can be available. If the PCM playback path is disabled (*PCM_RX_EN* = 0), a zero code value is driven into the speaker amplifier path.

The device also supports an audio processing bypass path from the PCM input to speaker amplifier output that bypasses the audio processing blocks like the volume control, DHT, BPE, and thermal foldback circuits. The audio processing bypass path is enabled by setting the *PCM_BYP_EN* bit field to 1. The PCM data input for the audio processing bypass path is selected with the *PCM_BYPASS_SOURCE* bit field. If the PCM audio processing bypass path is disabled (*PCM_BYP_EN* = 0), a zero code value is driven into the audio processing bypass path.

PCM Data Output

The PCM interface data output (DOUT) is enabled by the *PCM_TX_EN* bit field, and can transmit any output data type onto any valid output channel or slot. In I^2S and left-justified mode, only two data output channels are available in each output transmit frame (Channel 0 and 1). In TDM mode, each output transmit frame can contain up to 64 sequential 8-bit data output slots, each of which are numbered from 0 up to a maximum of 63.

The PCM data output can transmit several different output data types. In I^2S and left-justified modes, only the speaker amplifier output voltage sense, output current sense, and DSP monitor output data types are available for data output transmission. If the word size of the data output type is longer than output channel data word (*PCM_CHANSZ*), the lowest trailing bits are truncated.

In TDM mode, all output data types are available and are individually assigned to data output slots. The output data types vary in word size from 3 bits to 32 bits, and as a result require from 1 to 4 data output slots to transmit in TDM mode. Table 6 shows the supported output data types and the parameters of each data type.

Table 6. Supported PCM Data Output Types

OUTPUT DATA TYPE	SYMBOL	DATA WORD SIZE (BITS)	NUMBER OF TDM SLOTS	ENABLE/SLOT ASSIGNMENT
Speaker Amplifier Output Voltage Sense	VMON	16	2	*PCM_VMON_EN*/ *PCM_VMON_SLOT*
Speaker Amplifier Output Current Sense	IMON	16	2	*PCM_IMON_EN*/ *PCM_IMON_SLOT*
Speaker Amplifier DSP Monitor	DSPMON	32	4	*PCM_DSPMONITOR_EN*/ *PCM_DSP_MONITOR_SLOT*
Applied DHT Attenuation	DHT_ATN	16	2	*PCM_DHT_ATN_EN*/ *PCM_DHT_ATN_SLOT*
Battery Voltage (V_{VBAT})	VBAT	16	2	*PCM_VBAT_EN*/ *PCM_VBAT_SLOT*
PVDD Voltage (V_{PVDD})	PVDD	16	2	*PCM_PVDD_EN*/ *PCM_PVDD_SLOT*
BPE Level	BPELVL	3	1	*PCM_BPE_EN*/ *PCM_BPE_SLOT*
Device Status Flags	FLAG	14	2	*PCM_STATUS_EN*/ *PCM_STATUS_SLOT*

An individual enable and slot assignment bit field is provided for each output data type. In I^2S and left-justified modes, use output slot 0 to assign data to Channel 0 and output slot 1 to assign data to Channel 1. In TDM mode, the slot assignment selects the slot where the output data type transmit begins for data output types requiring more than one slot to transmit (e.g., a two slot data type assigned to slot 6 would occupy slots 6 and 7).

In TDM mode, each data type can be assigned to any valid data output slot (or series of slots) with some restrictions. First, it is invalid for data types to be assigned such that the data word extends beyond the end of the data output frame. For example, data types that require two slots to transmit cannot be assigned to the last slot of the frame. Next, it is also invalid to assign a data output type to any slot that overlaps with the slot assignment of another data type (this also applies to channels in I^2S and left-justified modes). Finally, it is invalid to assign a data type to any slots that do not exist in the frame structure of the current PCM interface configuration.

Any data output (DOUT) slots that exist in the current frame structure but have no output data type assigned to them are either Hi-Z or driven with a 0 code (as set by the *PCM_TX_SLOT_HIZ* bit field). Likewise, if a data output type is disabled, then the assigned data output slot(s) are also either Hi-Z or driven with a 0 code (as set by the *PCM_TX_SLOT_HIZ* bit field).

Data Output Channel-Interleaved I/V Sense Data

In I^2S and left-justified use cases, the PCM interface limits the number of available data output channels to two making it impossible to fit amplifier output current and voltage sense data from stereo devices on a single shared data output (DOUT) line. For these cases, the data output can be configured to allow the current and voltage sense data types from a single device to share a single data output channel. To enable channel-interleaved mode, set the *PCM_TX_INTERLEAVE* bit high. Then assign the current and voltage sense data types to the same valid data channel (using *PCM_VMON_SLOT* and *PCM_IMON_SLOT*).

In this configuration, the current and voltage sense data types are frame interleaved on the assigned data output channel. The current and voltage sense data words are both 16-bits in length, and as a result if the channel length is longer than 16-bits the trailing padding bits are set to either Hi-Z or zero code depending on the state of the *PCM_TX_EXTRA_HIZ* bit field.

To identify the data type in channel-interleaved mode, the LSB of the 16-bit data word is dropped (truncated). The data word is then right shifted by a single bit, and the now vacant MSB is replaced with either a 0 to indicate voltage sense data or a 1 to indicate current sense data. For phase alignment, the voltage sense data for a single sampling instant is always transmitted in the assigned channel on the first frame, followed by the current sense data on the second frame. The MSB value and the transmission order allow the host to identify and phase-align the output data across frames.

Since the I/V sense data is frame interleaved, the sample rate for the PCM interface must be greater than that of the I/V sense ADCs by an integer ratio of 2. The example below shows a basic case where the sample rate of the PCM interface is twice that of the I/V sense ADCs.

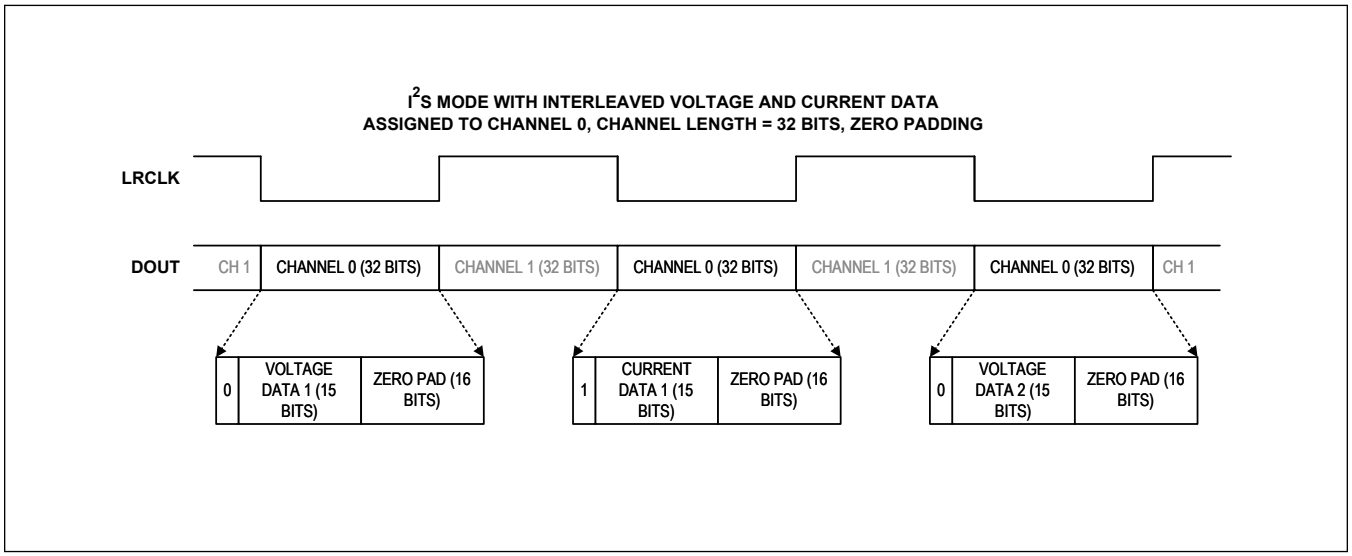

Figure 7. I/V Sense Path Data Interleaved on a Single Data Output Channel

Data Output Status Bits

The following interrupt information is reported in the status slots:

- Bit 15: BPE level 0 begin
- Bit 14: BPE level change
- Bit 13: BPE active begin
- Bit 12: BPE active end
- Bit 11: Thermal warning 1 begin
- Bit 10: Thermal warning 1 end
- Bit 9: Thermal warning 2 begin
- Bit 8: Thermal warning 2 end
- Bit 7: Thermal foldback begin
- Bit 6: Thermal foldback end
- Bit 5: DHT active end
- Bit 4: DHT active begin
- Bit 3: Speaker overcurrent
- Bit 2: Power-up done
- Bit 1: 0
- Bit 0: 0

Each of the interrupt information above corresponds to a raw interrupt and is 1 bit wide. When a raw interrupt has a rising edge, the corresponding status bit goes high during the next LRCLK frame. The status bit goes low during the next LRCLK frame even if the raw interrupt has remained high.

PCM Interface Timing

Figure 8 and Figure 9 shows timing for BCLK, LRCLK, DIN, and DOUT. See the Electrical Characteristics table for more details.

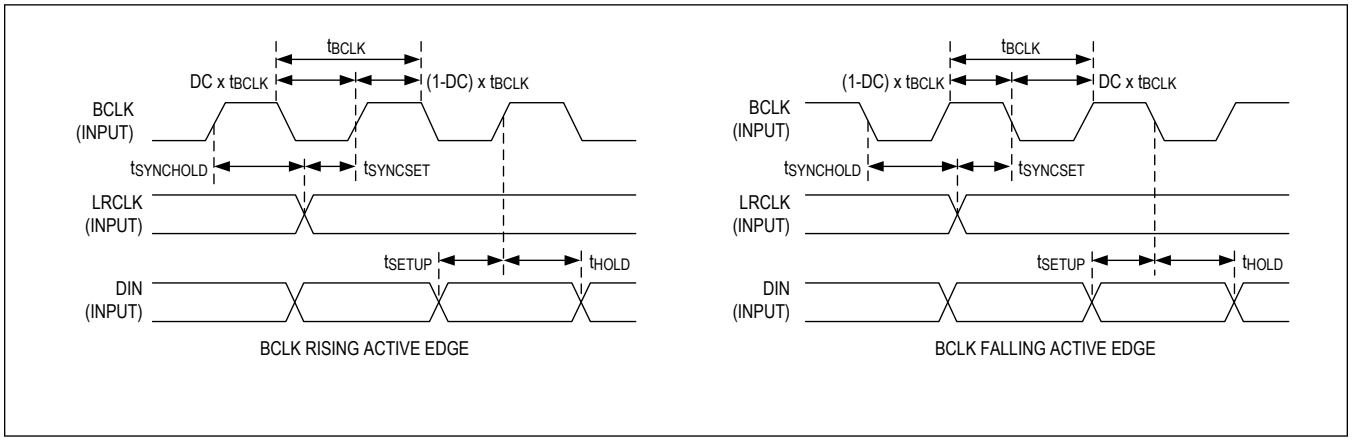

Figure 8. PCM Interface Timing/Slave Mode—LRCLK, BCLK, DIN Timing Diagram

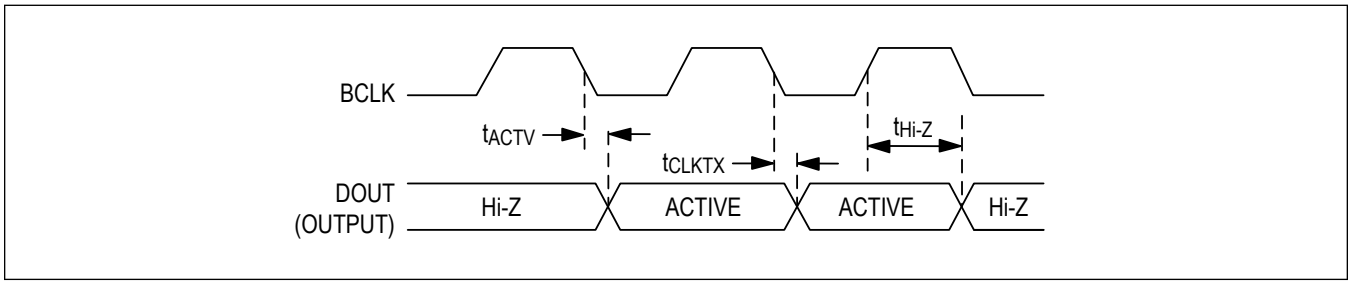

Figure 9. PCM Interface Timing/DOUT Timing Diagram

Interrupts

The device supports individually enabled status interrupts for sending feedback to the host about events that have occurred on-chip. When enabled, interrupts are transmitted on the IRQ output.

Interrupt Bit Field Composition

Each interrupt source has five individual bit field components. The function of each component is detailed as follows, and the corresponding bit fields for each source can be identified by the appended suffix (shown in parentheses).

- **Raw Status (RAW):** Each interrupt source has a read-only bit to indicate the real-time raw status of the interrupt source.
- **State (STATE):** Each interrupt source has a read-only state bit that is set whenever a rising edge occurs on the associated raw status bit. The state bit is set regardless of the setting of the source enable bit.
- **Flag (FLAG):** Each interrupt source has a read-only flag bit. If the source enable bit is set, then the flag bit is set and an interrupt can be generated whenever the source state bit is set.
- **Enable (EN):** Each interrupt source has a dynamic read/write enable bit. When the enable bit is set, the associated flag bit is set and an interrupt can be generated whenever the source state bit is set.
- **Clear (CLR):** Each interrupt source has a dynamic write-only clear bit. Writing a 1 to a clear bit resets the associated state and flag bits to 0. Writing a 0 to a clear bit has no effect. In I^2C control mode, the IRQ output is deasserted if all flag bits are 0.

Interrupt Output Configuration

The device allows the user to configure the drive mode, drive strength, and polarity of the IRQ output. The *IRQ_MODE* bit controls the drive mode. If *IRQ_MODE* is 0, the pin is configured as an open-drained output and requires an external pullup resistor. If *IRQ_MODE* is 1, then IRQ is configured as a push-pull CMOS output.

Additionally, when IRQ is configured as a push-pull CMOS output, the drive strength control (*IRQ_DRV*) bits set the drive strength of the IRQ output. Four different CMOS drive strengths are available.

The *IRQ_POL* bit controls the polarity of the IRQ bus. Interrupt events (a flag bit is set high) assert the IRQ bus low if *IRQ_POL* = 0 and high if *IRQ_POL* = 1. The IRQ bus deasserts if all flag bits are cleared (set low).

Interrupt Sources

Table 7. Interrupt Sources

INTERRUPT SOURCES	BIT FIELD	DESCRIPTION
Thermal Shutdown Begin Event	*THERMSHDN_BGN_**	Indicates when the thermal-shutdown threshold temperature has been exceeded.
Thermal Shutdown End Event	*THERMSHDN_END_**	Indicates that the die temperature was previously above the thermal-shutdown threshold and has now dropped below the threshold.
Thermal Warning 1 Begin Event	*THERMWARN1_BGN_**	Indicates when the thermal-warning1 threshold temperature has been exceeded.
Thermal Warning 1 End Event	*THERMWARN1_END_**	Indicates that the die temperature was previously above the thermal-warning1 threshold and has now dropped below the threshold.
Thermal Warning 2 Begin Event	*THERMWARN2_BGN_**	Indicates when the thermal-warning2 threshold temperature has been exceeded.
Thermal Warning 2 End Event	*THERMWARN2_END_**	Indicates that the die temperature was previously above the thermal-warning2 threshold and has now dropped below the threshold.
Thermal Foldback Begin Event	*THERMFB_BGN_**	Indicates that the die temperature is above the thermal-warning1 threshold and the device is attenuating the output.
Thermal Foldback End Event	*THERMFB_END_**	Indicates die temperature is below thermal-warning1 threshold and device has stopped attenuating the output.
BPE Level Change Event	*BPE_LEVEL_**	Indicates that the BPE has transitioned between thresholds.
BPE Active Begin Event	*BPE_ACTIVE_BGN_**	Indicates that the BPE is active.
BPE Active End Event	*BPE_ACTIVE_END_**	Indicates that the BPE is no longer active.
BPE Level 0 Begin Event	*BPE_L0_**	Indicates that the BPE has transitioned into L0.
OTP Load Fail Event	*OTP_FAIL_**	Indicates when the OTP load routine that runs when exiting hardware shutdown has failed to complete successfully. If the OTP load routine fails, the device is held in software shutdown.

Table 7. Interrupt Sources (continued)

Speaker Over Current Event	*SPK_OVC_**	Indicates that the speaker amplifier current limit has been exceeded.
Internal CLK Error	*INT_CLK_ERR_**	Indicates a clock stop error in the internal clocks of the device.
External CLK (BCLK/LRCLK) Error	*CLK_ERR_**	Indicates a frequency or framing error in the input BCLK or LRCLK.
External CLK (BCLK/LRCLK) Recover	*CLK_RECOVER_**	Indicates that the input BCLK or LRCLK has recovered after an error event.
Speaker Amplifier Monitor Error	*INT_SPKMON_ERR_**	Indicates an amplifier output stuck high or low error.
External Data (DIN) Error	*DMON_ERR_**	Indicates a data stuck or data magnitude error at the PCM data input (DIN).
Power-Up Done Event	*PWRUP_DONE_**	Indicates when the device has entered the active state and the device is ready to play audio.
Power-Down Done Event	*PWRDN_DONE_**	Indicates when the device has entered the software shutdown state.
PVDD UVLO Shutdown Event	*PVDD_UVLO_SHDN_**	Indicates that PVDD is below the minimum allowed voltage when the device is in active state.
VBAT UVLO Shutdown Event	*VBAT_UVLO_SHDN_**	Indicates that VBAT is below the minimum allowed voltage when the device is in active state.
DHT Active Begin Event	*DHT_ACTIVE_BGN_**	Indicates that the DHT circuit is active and is applying attenuation to the signal.
DHT Active End Event	*DHT_ACTIVE_END_**	Indicates that the DHT circuit has stopped applying attenuation to the signal.
NOTE: The bit fields are shown without the component suffixes. For example, OTP_FAIL_* refers to OTP_FAIL_RAW, OTP_FAIL_STATE, OTP_FAIL_FLAG, OTP_FAIL_EN, and OTP_FAIL_CLR. All interrupt sources have these five component bit fields.		

Speaker Path

Speaker Path Block Diagram

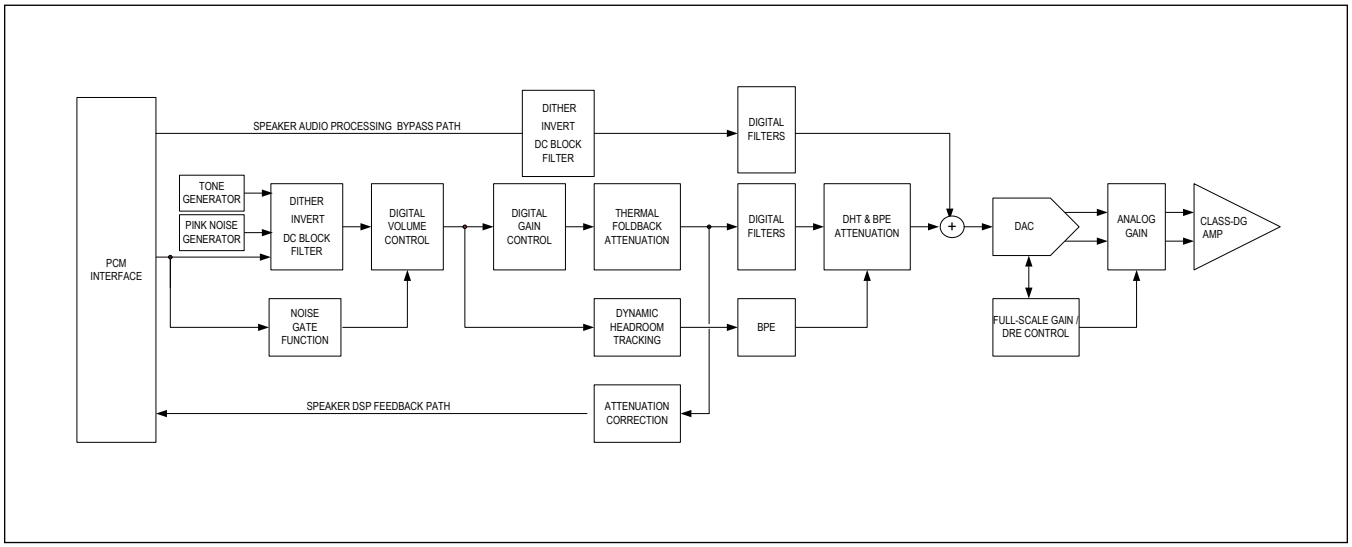

Figure 10. Speaker Signal Path Diagram

Speaker Playback Path

The source input data to the speaker amplifier path is routed from either the PCM interface or the tone generator. The data is then routed through digital filters, signal processing, and volume/gain control blocks before reaching the Class-DG speaker amplifier.

Speaker Path Noise Gate

The speaker path noise gate function is enabled when the device is in the active state and the noise gate enable (*NOISEGATE_EN*) is set to 1. The noise gate enable can be programmed dynamically. However, if the noise gate function is disabled (*NOISEGATE_EN* is set to 0) while the noise gate is active (speaker path actively muted), the noise gate function remains active until after it deactivates normally (unmutes the speaker path).

When the noise gate is enabled, the noise gate activates whenever the amplitude of the input audio data to the speaker path (from the PCM interface) is below the configured mute threshold (*MUTE_THRESH*) for more than 1024 consecutive data samples. When the noise gate is active, the amplifier path is muted, the current and voltage sense ADC paths output zero code data, and the device idles in a reduced power state.

The noise gate deactivates immediately if the amplitude of a single sample from the input audio data exceeds the configured unmute threshold (*UNMUTE_THRESH*). When the noise gate deactivates, the speaker path is unmuted and returns to normal operation before the input audio data (that triggered deactivation) reaches the speaker output. Once noise gate deactivation is complete, the current and voltage sense ADC paths resume operation and output data normally.

The noise gate mute and unmute threshold settings are selected in terms of the number of bits (starting from the LSB) that must be toggling (or active) in order for the input signal amplitude to exceed the thresholds. It is invalid to set the noise gate unmute threshold (*UNMUTE_THRESH*) such that it is less than the configured mute threshold (*MUTE_THRESH*). The location of the audio data LSB within the PCM input data channel is determined by the configured PCM data word size (*PCM_CHANSZ*). The supported combinations are shown in Table 8.

Table 8. Noise Gate/Idle Mode Threshold LSB Location by Input Data Configuration

INPUT DATA WORD SIZE (*PCM_CHANSZ*)	NOISE GATE FUNCTION LSB LOCATION
16	16
24	24
32	

It is not valid to enable the speaker path noise gate function when the tone generator is enabled or when the speaker idle mode is enabled.

Speaker Path Dither

The input data to the speaker path can optionally have dither (±1LSB peak-to-peak) applied if *SPK_DITH_EN* is set to 1. No dither is applied when *SPK_DITH_EN* is set to 0.

Speaker Path Data Inversion

The input data to the speaker path can optionally be inverted by setting the *SPK_INVERT* bit to 1. The input data to the speaker path can only be inverted when the speaker DC blocking filter is also enabled by setting *SPK_DCBLK_EN* to 1.

Speaker Path DC Blocking Filter

A DC blocking filter can be enabled on the speaker path by setting the *SPK_DCBLK_EN* bit to 1.

Speaker Path Digital Volume Control

The device has a dynamically programmable speaker path digital volume control. The digital volume control provides an attenuation range of 0dB to -63dB in 0.5dB steps that is configured with the *SPK_VOL* bit field. A digital mute is also provided, and is enabled when *SPK_VOL* is set to 0x7F.

Digital volume ramping during speaker path start up, speaker path shutdown, and digital mute (*SPK_VOL* = 0x7F) is disabled by default. However, both the volume ramp up and ramp down can be individually enabled with the *SPK_VOL_RMPUP_BYPASS* and *SPK_VOL_RMPDN_BYPASS* bit fields respectively. When volume ramp up or ramp down is enabled, the device turn-on and turn-off times are longer.

Speaker Path Digital Gain Control

The device provides a programmable speaker path digital gain control. The digital gain control provides a range of 0dB to +6dB in 0.5dB steps that is configured with the *SPK_GAIN* bit field. Unlike the digital volume control, the digital gain setting cannot be dynamically changed.

Speaker Path DSP Data Feedback Path

The speaker path DSP data can be routed from just before the DAC input back to the PCM interface, and can be assigned to any valid data output channel. The speaker path DSP data feedback path is enabled with the *SPK_FB_EN* bit.

Speaker Safe Mode

The device provides a safe mode bit (*SPK_SAFE_EN*) which applies a -18dB attenuation to the input signal when set to 1. By default, speaker safe mode is enabled to protect any speaker connected to the device on power-up. While speaker safe mode is enabled, the digital volume control (*SPK_VOL*) and speaker digital gain control (*SPK_GAIN*) settings are ignored.

Speaker Audio Processing Bypass Path

In applications where the audio processing in the main speaker path is not desired, the device provides a bypass path. The bypass path is selected with the *PCM_BYPASS_EN* bit field. The PCM data input channel for the speaker audio processing bypass path is selected with the *PCM_BYPASS_SOURCE* bit field.

Bypass Path Data Inversion

The input data to the audio processing bypass path can optionally be inverted by setting the *BYP_INVERT* bit to 1. The input data to the audio processing bypass path can only be inverted when the DC blocking filter is also enabled by setting *SPK_DCBLK_EN* to 1.

Bypass Path Dither

The input data to the audio processing bypass path can optionally have dither (±1LSB peak-to-peak) applied if *SPK_DITH_EN* is set to 1. No dither is applied when *SPK_DITH_EN* is set to 0. The *SPK_DITH_EN* bit also controls the dither applied to the audio playback path.

Bypass Path DC Blocking Filter

A DC blocking filter can be enabled on the audio processing bypass path by setting the *SPK_DCBLK_EN* bit to 1. The *SPK_DCBLK_EN* also controls the DC blocking filter in the audio playback path.

Speaker Maximum Peak Output Voltage Scaling

The device operates over a large PVDD supply voltage range, and as a result the full-scale speaker amplifier output amplitude level is configurable to allow it to be scaled. As a baseline, the full-scale output of the speaker path DAC is 3.68dBV (typ). The speaker path no-load maximum peak output voltage level (V_{MPO}) is then programmable relative to this baseline level. The peak output scaling range is from +4dB to +21dB, and is set with the *SPK_GAIN_MAX* bit field.

The speaker output signal level (in dBV) for a given digital input signal level (in dBFS) is calculated as follows:

Output Signal Level (dBV) = Input Signal Level (dBFS) + 3.68 (dBV) + SPK_GAIN_MAX (dB)

(0dBFS is referenced to 0dBV)

The peak output voltage scaling is applied to the signal path using a combination of digital gain and analog gain adjustments.

Dynamic-Headroom Tracking (DHT)

The device features dynamic-headroom tracking that can preserve consistent signal distortion and listening levels in the presence of a varying supply level. The DHT block provides both a dynamic range compressor (DRC) and limiter. The limiter can operate either as a signal distortion limiter (SDL) or a standard signal level limiter (SLL). Each of these three functions can be used independently (modes 1 through 3), and the SLL and DRC can be used simultaneously (mode 4). The DHT block is enabled with the *DHT_EN* bit. Prior to enabling the DHT, the measurement ADC, PVDD, and VBAT channels should be configured and enabled as required based on the amplifier mode of operation. The DHT block uses the measured supply levels and the current signal level to calculate the attenuation (if any) that is applied to the signal path. Also, the DHT block should not be disabled by setting *DHT_EN* bit to 0 when the DHT is active (i.e., attenuation is being applied).

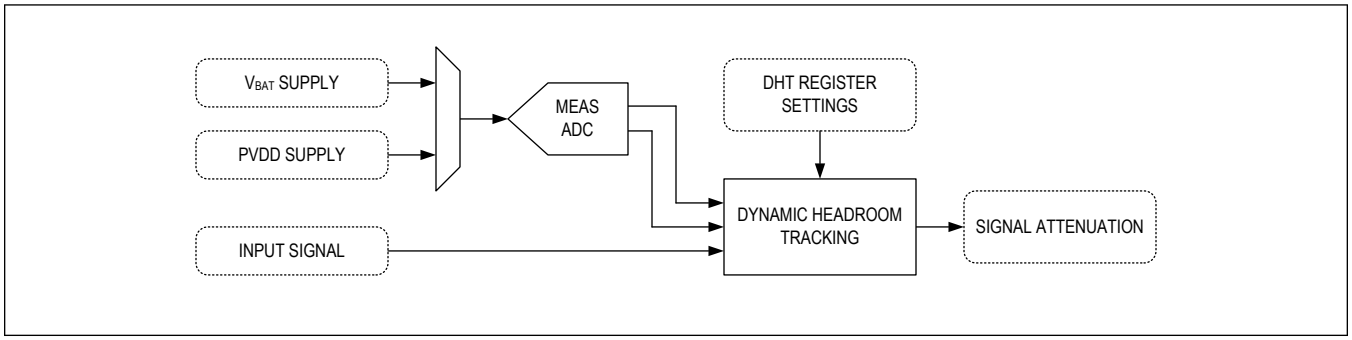

Figure 11. Simplified Dynamic-Headroom Tracking System Block Diagram

DHT Supply Tracking and Headroom

The DHT block uses three parameters to track the target peak output level (V_{TPO}) relative to the maximum peak output voltage (V_{MPO}) as the active speaker amplifier supply level varies.

The first is the speaker amplifier full-scale gain setting (*SPK_GAIN_MAX* bit field). This control selects the maximum (no-load) peak output voltage level (V_{MPO}) that is output by the Class-DG amplifier with a full-scale input signal (0dBFS). Most DHT thresholds and parameters are calculated relative to the full-scale V_{MPO}.

The second parameter is the measured speaker amplifier supply voltage level (V_{SUP}). The measurement ADC provides the DHT block with the current supply voltage levels (V_{PVDD} and V_{VBAT}). The DHT block decides which supply voltage to use for calculations based on the currently active speaker amplifier supply.

The third parameter is the speaker amplifier supply headroom (SUP_{HR}). The supply headroom is a positive or negative percentage offset relative to the measured V_{SUP} conversion result. It is configured using the *DHT_HR* bit field, and can be set from +20% to -20% of V_{SUP} in 2.5% step sizes.

The DHT target peak output voltage level (V_{TPO}) is equal to the measured supply voltage (V_{SUP}) scaled to include the selected supply headroom percentage and is actively calculated with the following equation:

$V_{TPO} = V_{SUP} \times (100\% - SUP_{HR})$ The target peak output attenuation (or ratio) from V_{TPO} to V_{MPO} is calculated as follows:

$A_{TPO} = 20 \times \log (V_{TPO}/V_{MPO})$

If A_{TPO} exceeds 0dB (V_{SUP} with headroom > V_{MPO}), then the DHT block assumes that there is sufficient supply voltage to reproduce the audio signals as configured without attenuation. In this case, A_{TPO} = 0dB is used for all further calculations. This is important as the DHT functions only ever apply attenuation and do not apply positive gain. Once the calculated V_{TPO} drops below V_{MPO}, the calculated target peak output attenuation (A_{TPO}) is less than 0dB, and the DHT functions are applied appropriately as the input signal level changes.

For example, if V_{MPO} = 13.63V, V_{SUP} = 8.04V, and SUP_{HR} = -20%, then solving for V_{TPO} yields a target peak output level of approximately 9.65V. Next, solving for the target peak output attenuation (A_{TPO}) yields approximately -3dB.

Figure 12 shows the default transfer function (with no DHT attenuation applied), where the current target peak output level (V_{TPO}) is based on the current V_{SUP} and the supply headroom settings. The tracked V_{TPO} and the resulting peak output attenuation (A_{TPO}) are then used in the attenuation calculations for the DHT functions. Note that this and all subsequent figures are not drawn to precise scale, and that the x-axis is input signal level (dBFS) on a linear scale, while the y-axis is peak output voltage level on a log scale.

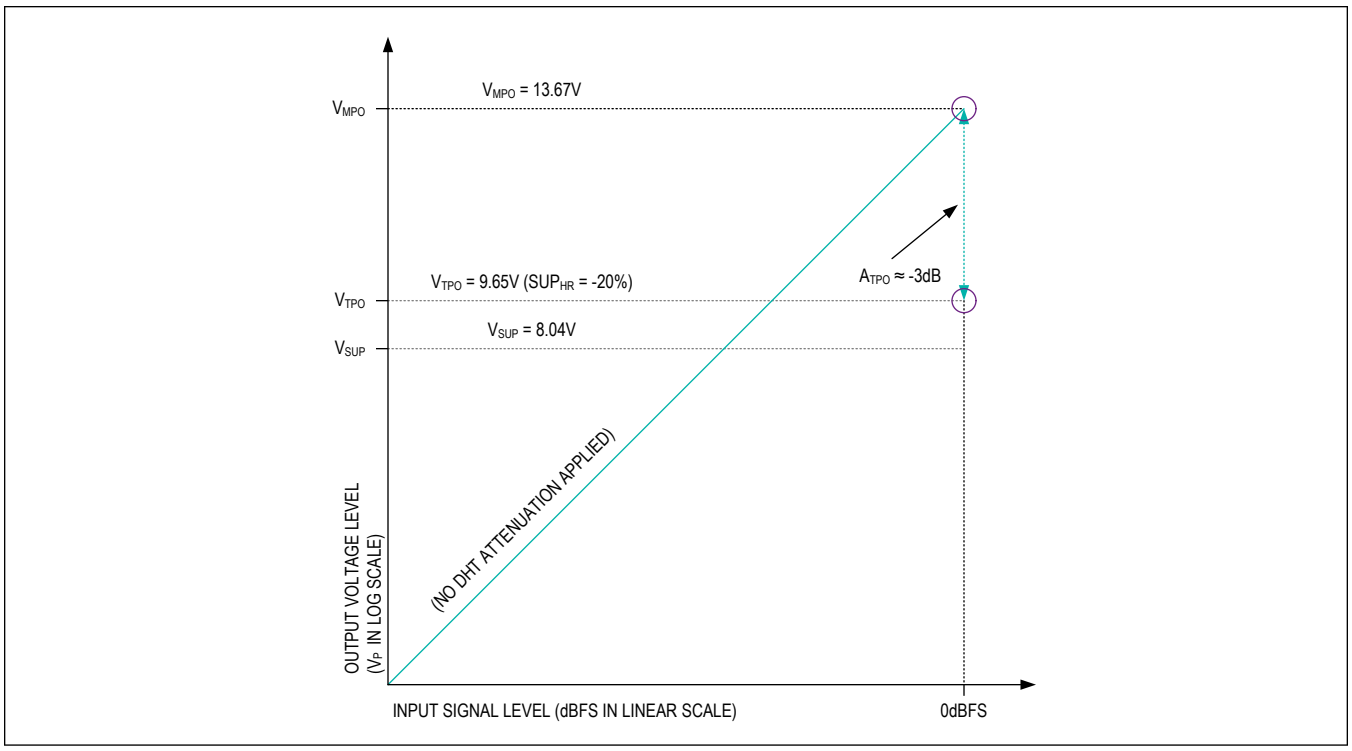

Figure 12. V_{TPO} and A_{TPO} Calculation Example

DHT Mode 1 – Signal Distortion Limiter

The DHT signal distortion limiter (SDL) maintains a consistent level of signal distortion at the amplifier output as the supply voltage (V_{SUP}) changes. To use DHT mode 1 (just the signal distortion limiter active), set the *DHT_LIM_MODE* bit low (default) to place the limiter function in supply tracking mode (SDL), and set the dynamic range compressor rotation point (*DHT_VROT_PNT*) to 0dBFS (effectively disabling the DRC). The signal distortion limiter function is a compressor with a ratio of infinity to one that actively sets its threshold (V_{SDL} in voltage) equal to the calculated target peak output voltage level (V_{TPO}). The output referred SDL threshold (SDL_{THR}) and the input referred SDL knee or rotation point (SDL_{RP}) are equal in mode 1, and can be calculated relative to full-scale (in dBFS) as a ratio of V_{TPO} to V_{MPO}:

$$SDL_{RP} = SDL_{THR} = 20 \times \log(A_{TPO}) = 20 \times \log(V_{TPO} / V_{MPO})$$

The transfer function for input signal levels below the SDL rotation point (SDL_{RP}) is unchanged. When the input signal level exceeds SDL_{RP}, the signal distortion limiter function is applied to the signal path. As the input signal level increases, the distortion limiter attenuation continues to increase as well and can be calculated for a given input signal level (A_{INPUT} in dBFS) as follows:

$$SDL\ ATTENUATION = SDL_{RP} - A_{INPUT}$$

By actively recalculating SDL_{RP} (or SDL_{THR}) as the target peak output level (V_{TPO}) changes, the DHT SDL maintains a consistent limit and level of amplifier output distortion relative to available supply voltage (V_{SUP}).

When the target peak output voltage (V_{TPO}) exceeds the amplifier maximum peak output voltage (V_{MPO}) there is sufficient headroom and no SDL attenuation is applied. However, as soon as V_{TPO} falls below V_{MPO}, it is possible for the input signal amplitude to exceed the calculated SDL_{RP}. The following examples show the transfer function when $V_{SUP} \geq V_{MPO}$ with the minimum (-20%), without (0%), and maximum (+20%) supply headroom (SUP_{HR}) settings. Note that in the case with positive headroom (+20%), the SDL_{RP} falls below the input signal full-scale level even though $V_{SUP} = V_{MPO}$.

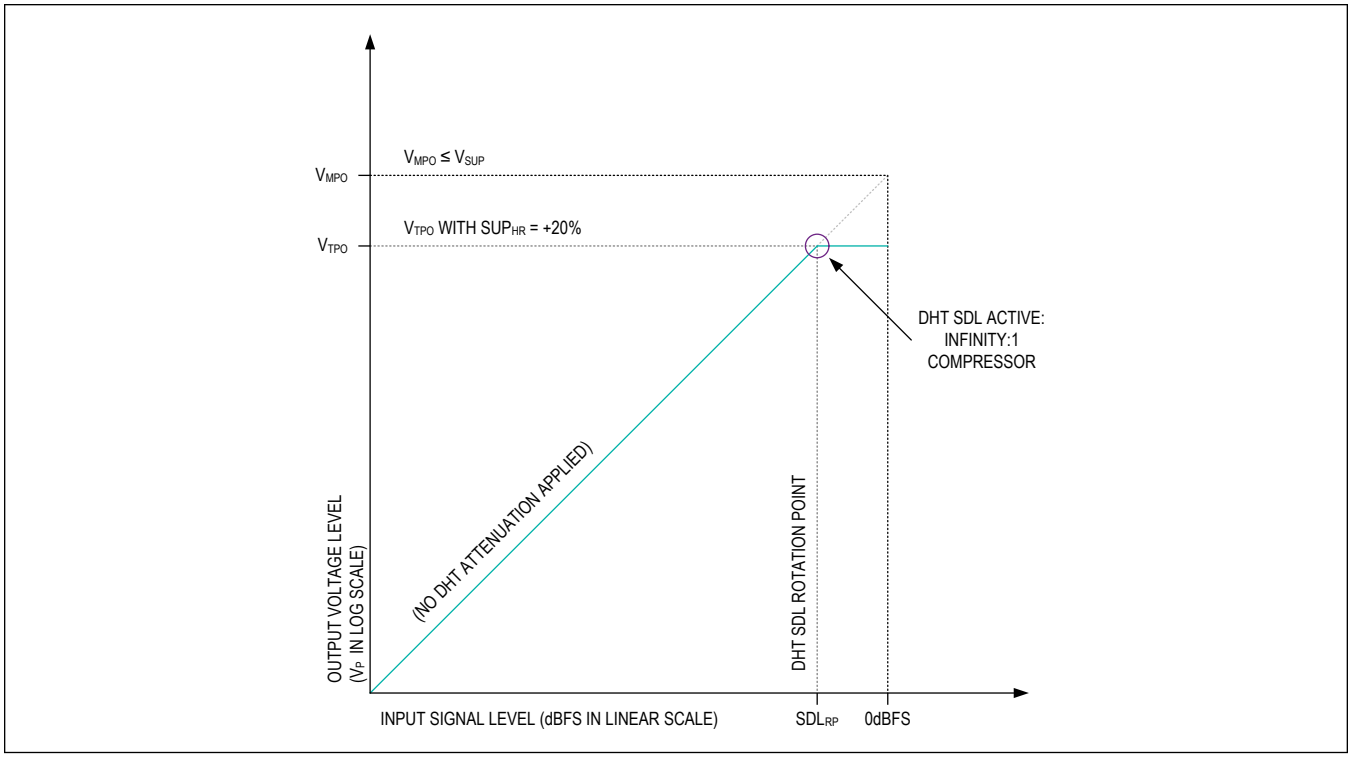

Figure 13. Signal Distortion Limiter with $V_{MPO} \leq V_{SUP}$ and +20% Headroom (SUP_{HR})

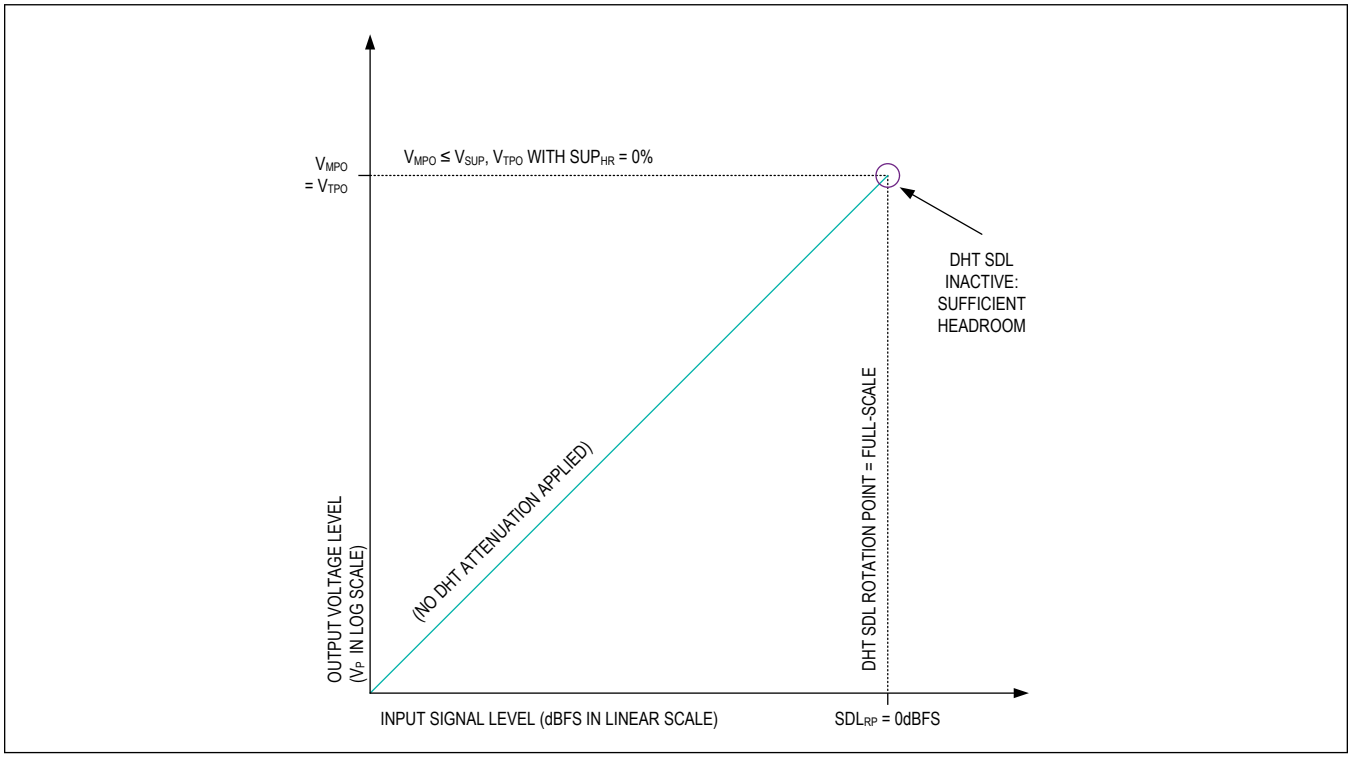

Figure 14. Signal Distortion Limiter with $V_{MPO} \leq V_{SUP}$ and 0% Headroom (SUP_{HR})

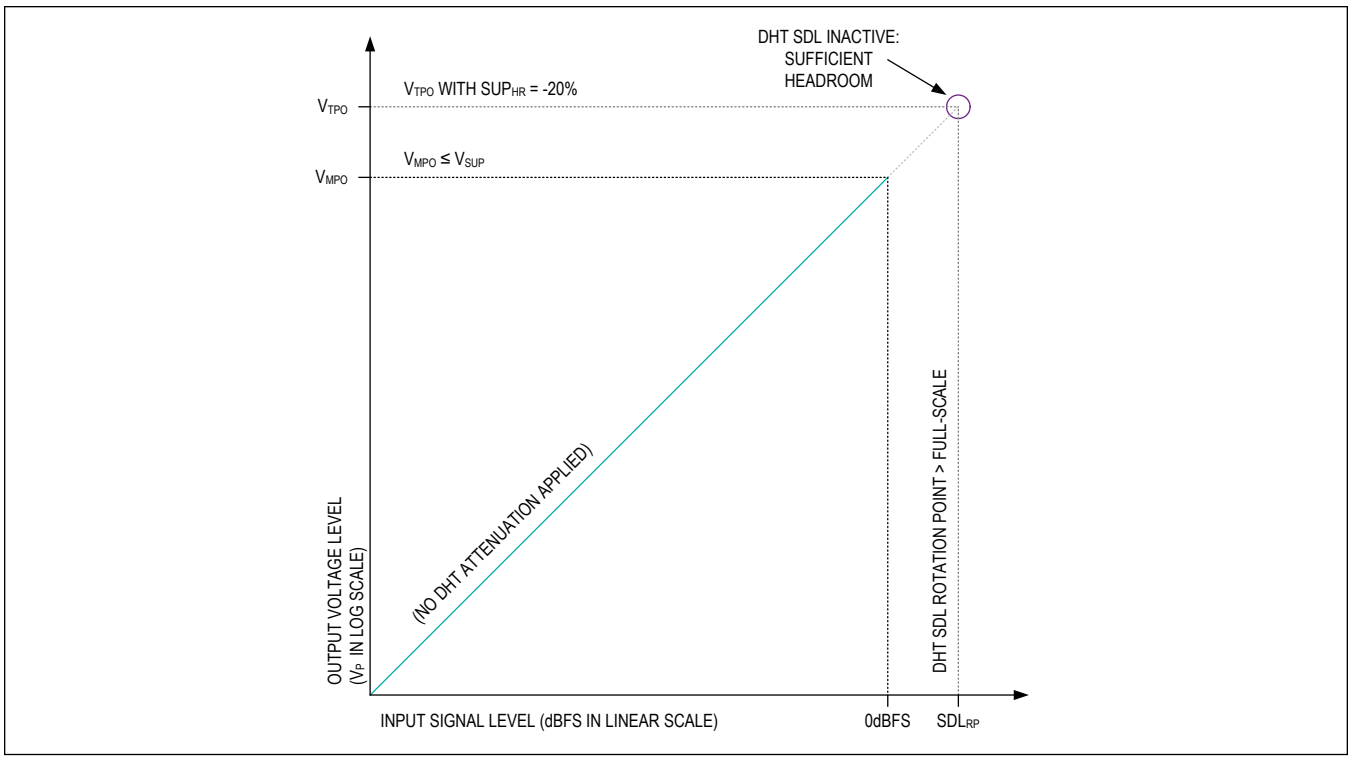

Figure 15. Signal Distortion Limiter with $V_{MPO} \leq V_{SUP}$ and -20% Headroom (SUP_{HR})

As the supply voltage (V_{SUP}) drops further below the maximum peak output voltage (V_{MPO}), the DHT target peak out voltage (V_{TPO}) proportionally scales down. In cases with zero or positive amplifier supply headroom settings (+20% ≥ SUP_{HR} ≥ 0%), the input signal level can exceed the SDL rotation point (SDL_{RP}) before the peak output exceeds V_{SUP}. In this case, amplifier output clipping can be prevented.

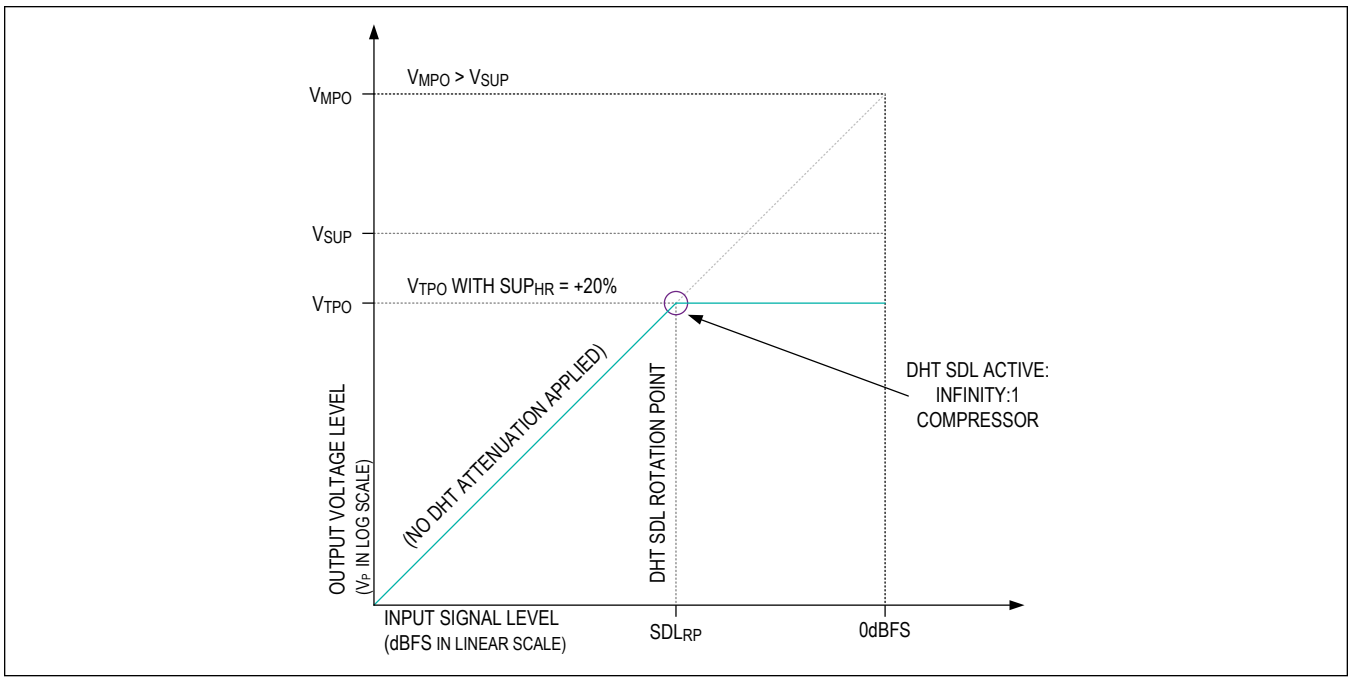

Figure 16. Signal Distortion Limiter with V_{MPO} > V_{SUP} and +20% Headroom (SUP_{HR})

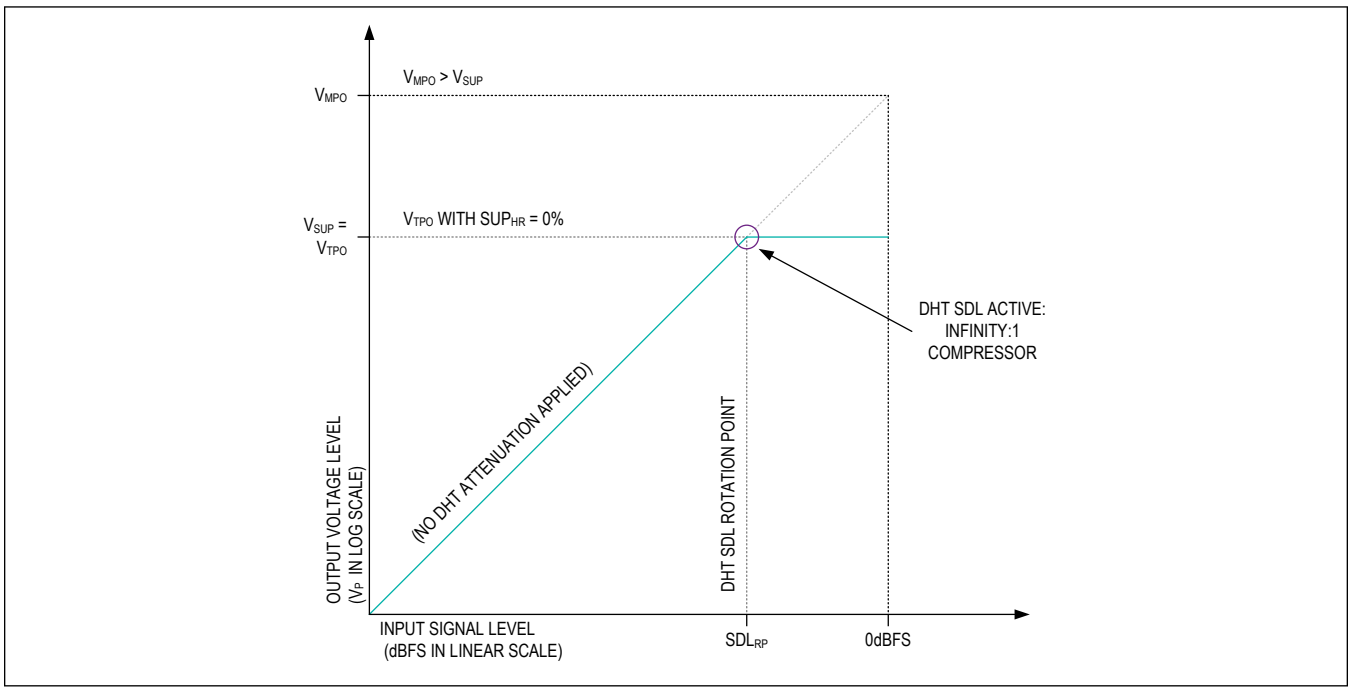

Figure 17. Signal Distortion Limiter with V_{MPO} > V_{SUP} and 0% Headroom (SUP_{HR})

In cases with a negative supply headroom setting (0% > SUP_{HR} ≥ -20%), the input signal does not exceed the SDL_{RP} until after the peak output reaches V_{SUP}. As a result, clipping occurs at the amplifier output. However, once the input signal level exceeds the SDL_{RP}, the audio signal level is digitally limited by the SDL preventing the amplifier output clipping from worsening further.

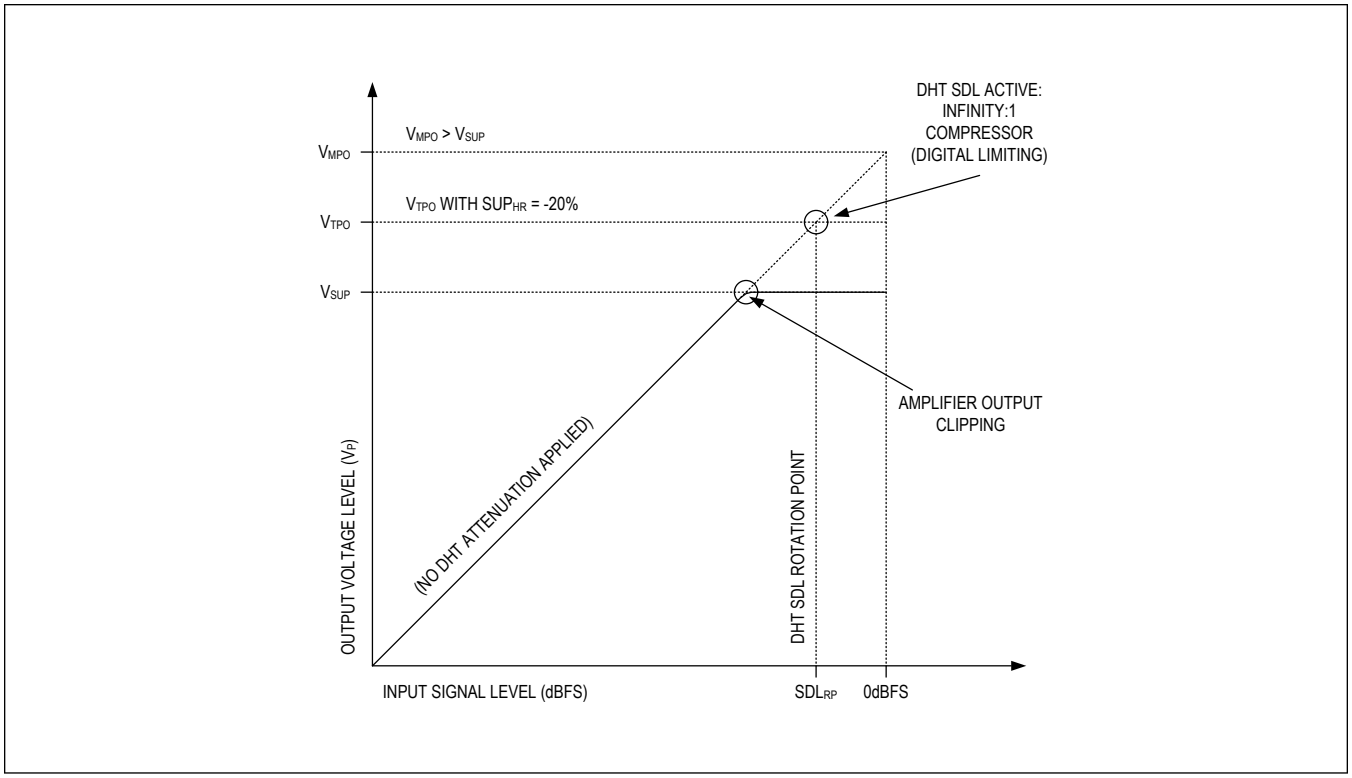

Figure 18. Signal Distortion Limiter with V_{MPO} > V_{SUP} and -20% Headroom (SUPHR)

DHT Mode 2 – Signal Level Limiter

In DHT mode 2, the limiter is configured as a fixed threshold signal level limiter (SLL). Set the *DHT_LIM_MODE* bit high to place the limiter function in SLL mode, and set the dynamic range compressor rotation point to 0dBFS (effectively disabling the DRC).

Like the signal distortion limiter, the signal level limiter function is a compressor with a ratio of infinity to 1. However, unlike the SDL, the SLL output referred threshold (SLL_{THR}) is configured to a set level. The SLL_{THR} is selected with the *DHT_LIM_THRESH* bit field from a range of 0dBFS to -15dBFS. The SLL threshold can also expressed as an input referred knee or rotation point (SLL_{RP}) which is equal to SLL_{THR} in mode 2. The SLL amplifier peak output voltage limit (V_{SLL}) is calculated from the selected SLL threshold (SLL_{THR}) and maximum peak output voltage (V_{MPO}) with the following equation:

$$\text{SLL PEAK OUTPUT VOLTAGE LIMIT} = V_{SLL} = V_{MPO} \times 10^{(SLL_{THR} / 20)}$$

The transfer function for signal levels below the SLL threshold (SLL_{THR}) is unchanged. When the signal level exceeds the SLL_{THR}, the signal level limiter function is applied to the signal path. As the input signal level increases, the limiter attenuation continues to increase as well and can be calculated for a given input signal level (A_{INPUT} in dBFS) relative to SLL_{RP} (= SLL_{THR}) as follows:

$$\text{SLL ATTENUATION} = SLL_{RP} - A_{INPUT}$$

When V_{TPO} is greater than V_{SLL}, the amplifier peak output level is limited to V_{SLL} whenever the signal amplitude exceeds the SLL threshold (SLL_{THR}). As a result of the fixed SLL threshold and rotation point, the transfer function is identical for any V_{SUP} level and corresponding V_{TPO} that is greater than V_{SLL}.

This is illustrated in Figure 19 for decreasing V_{SUP} and V_{TPO} levels. As V_{SUP} decreases, V_{TPO} is recalculated and decreases as well. Three different progressively lower V_{TPO} levels are shown (V_{TPO1}, V_{TPO2}, and V_{TPO3}). Due to the fixed SLL threshold, V_{SLL} is the same in all three cases. Since all three V_{TPO} values are greater than V_{SLL}, the transfer function for each case is identical and is limited at V_{SLL}.

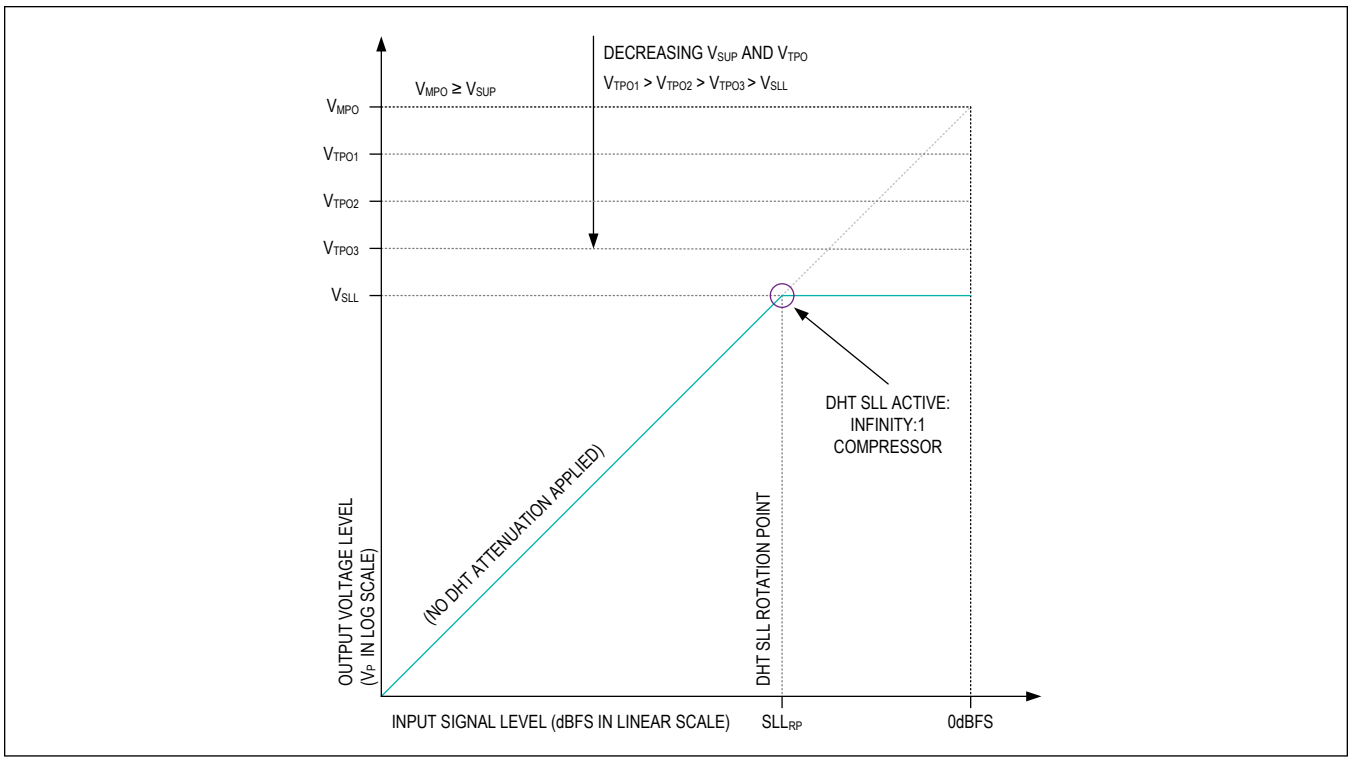

Figure 19. Signal Level Limiter with $V_{TPO} > V_{SLL}$ as V_{SUP} Decreases

When V_{TPO} is less than V_{SLL}, the amplifier output can clip before the input signal amplitude exceeds the SLL rotation point ($SLL_{RP} = SLL_{THR}$). As the input signal level continues to increase and exceed SLL_{RP}, the signal level is digitally limited which prevents the amplifier output clipping from worsening further. Because both the SLL threshold and rotation point are fixed relative to full-scale, the clipping at the amplifier output grows progressively worse prior to the input signal exceeding SLL_{RP} (= SLL_{THR}) as V_{SUP} continues to decrease.

The following [[Signal Level Limiter with V_{TPO}< V_{SLL} Showing Amplifier Output Clipping]] has the same SLL settings as Figure 19 (same SLL_{THR}). For simplicity, V_{TPO} = V_{SUP} (SUP_{HR} = 0%), and V_{TPO} has decreased further and is now less than V_{SLL}. As a result, the amplifier output clips before the SLL digitally limits the signal level.

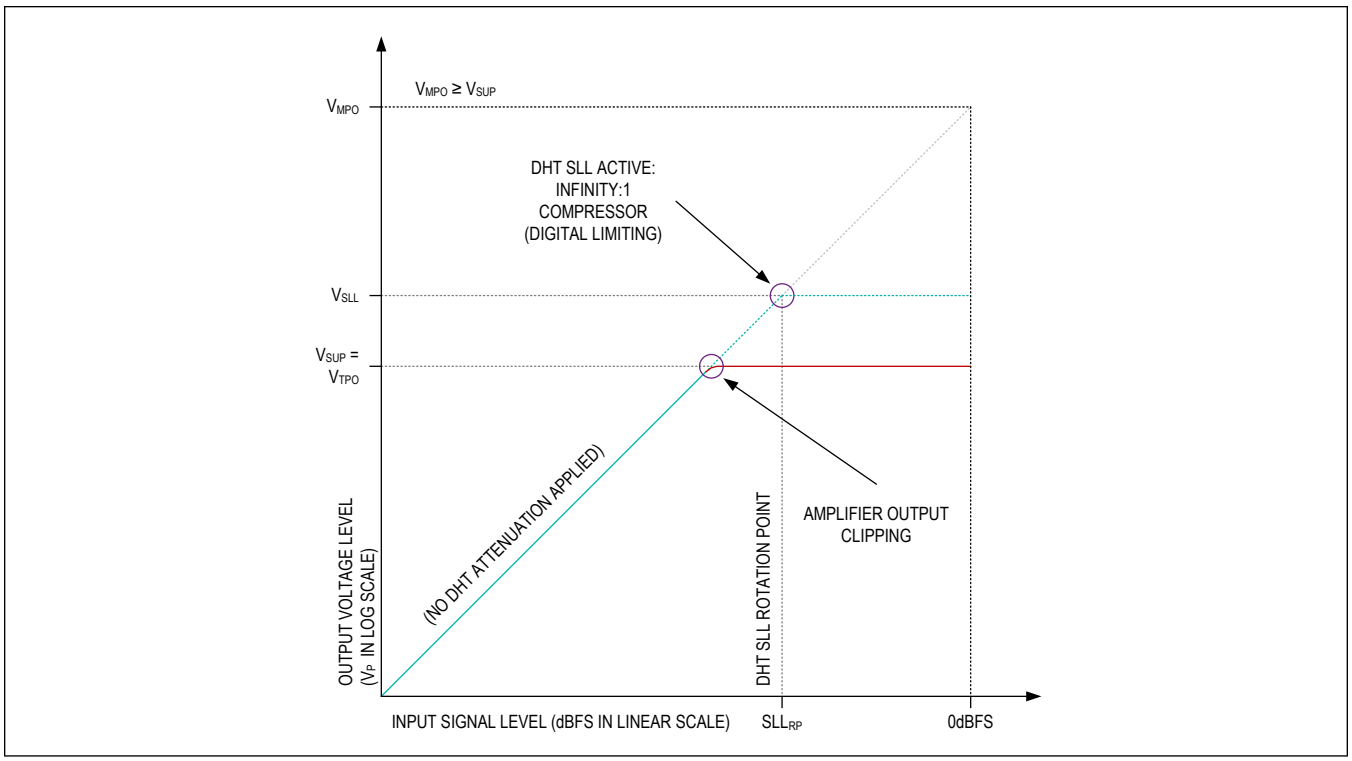

Figure 20. Signal Level Limiter with V_{TPO} < V_{SLL} Showing Amplifier Output Clipping

DHT Mode 3: Dynamic Range Compressor

The DHT dynamic range compressor (DRC) is configured by setting the input referred rotation point (DRC_{RP} in dBFS). The DRC_{RP} can be selected from a range from 0dBFS to -15dBFS with the *DHT_VROT_PNT* bit field. To calculate the DRC output referred voltage threshold (V_{DRC}), use the following equation:

$$V_{DRC} = V_{MPO} \times 10^{(DRC_{RP}/20)}$$

For mode 3 operation, set the DRC rotation point (DRC_{RP}) to any level lower than 0dBFS. Next, to disable limiter functions, place DHT into signal level limiter mode (*DHT_LIM_MODE* = 1) and set the fixed SLL threshold (SLL_{THR}) to 0dBFS (using the *DHT_LIM_THRESH* bit field).

Once configured, the dynamic range compressor rotation point (DRC_{RP}) is fixed at the selected level (or ratio) relative to the input full-scale. As V_{SUP} and V_{TPO} change, the DRC compression ratio for input signals that exceed DRC_{RP} changes as well. However, the transfer function remains unchanged for input signals below DRC_{RP}. If the amplifier is operating in class-G mode, it is recommended that the DRC rotation point (DRC_{RP}) be set such that V_{DRC} exceeds the maximum possible VBAT voltage level. This ensures that DRC compression is only applied when PVDD is the active amplifier supply, and that the DHT cannot rapidly switch between two different ratios if the active amplifier supply toggles quickly.

The DHT tracks the target peak output voltage (V_{TPO}) and attenuation (A_{TPO}). As they change, the adaptive DRC compression ratio smoothly scales the listening level of the amplifier for any input signals that exceed DRC_{RP}. The DRC compression ratio is actively calculated with the following formula:

$$\text{DRC COMPRESSION RATIO} = DRC_{RP}/(A_{TPO} - DRC_{RP})$$

The DRC attenuation for a given input signal level (A_{INPUT} in dBFS) is calculated as follows:

$$\text{DRC ATTENUATION} = ATPO - AINPUT \times (ATPO / DRCRP)$$

The following example shows the DRC transfer function with SUP_{HR} ≥ 0% as V_{SUP} (and thus V_{TPO}) decreases. As the V_{TPO} level decreases (from V_{TPO1} to V_{TPO2} to V_{TPO3}), the DRC compression ratio increases.

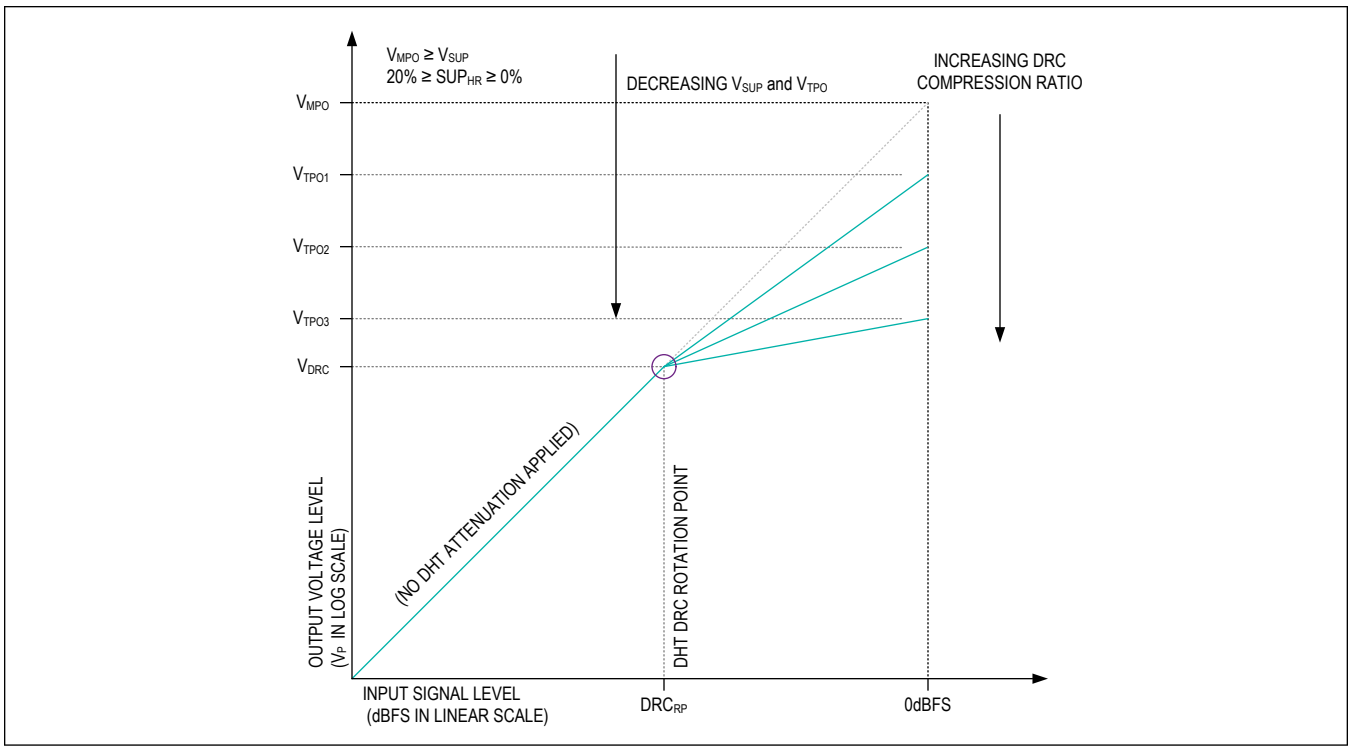

Figure 21. Dynamic Range Compression with Decreasing V_{SUP} and SUP_{HR} ≥ 0%

Figure 22 shows the DRC transfer function with SUP_{HR} < 0%. Due to the negative supply headroom, V_{TPO} is greater than V_{SUP} and the amplifier output clips before the input signal reaches full-scale.

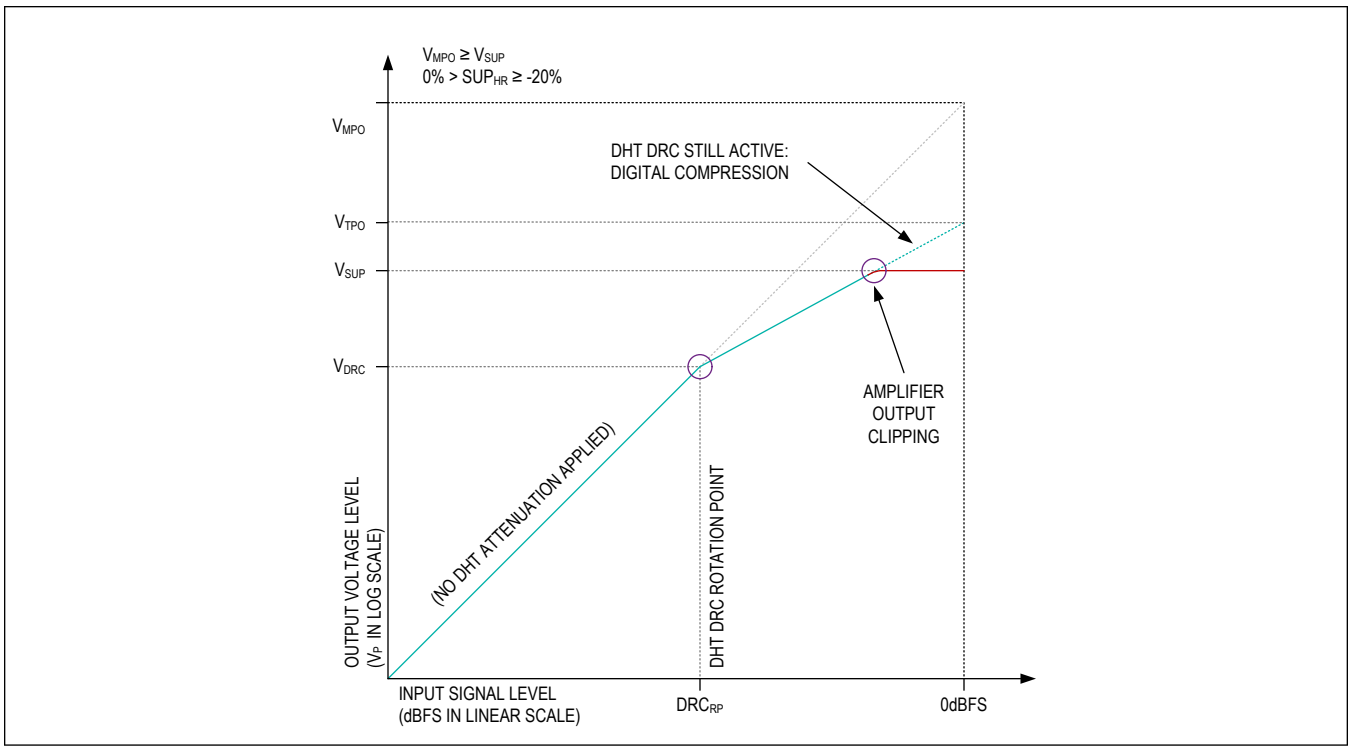

Figure 22. Dynamic Range Compressor with SUP_{HR} < 0% and Output Clipping

DHT Mode 4: Dynamic Range Compressor with Signal Level Limiter

In DHT mode 4, the dynamic range compressor (DRC) and signal level limiter (SLL) are both enabled. The DRC rotation point (DRC_{RP}) must be less than 0dBFS to enable mode 4. In addition, the DHT limiter function must be configured for SLL mode (*DHT_LIM_MODE* = 1) with an SLL threshold (SLL_{THR}) less than 0dBFS. Finally, to create a DHT response curve with both DRC and SLL inflection points, the SLL threshold (V_{SLL}) must be greater than the DRC voltage threshold (V_{DRC}). This insures that the resulting SLL_{RP} is always greater than the DRC_{RP}; otherwise, the SLL limits the signal level before the DRC rotation point is ever reached.

Figure 23 shows three mode 4 transfer functions for three progressively lower V_{SUP} levels. The supply headroom is configured for SUP_{HR} > 0% (positive supply headroom), and the calculated V_{TPO} value is falling such that V_{TPO1} > V_{TPO2} > V_{TPO3}. The DRC rotation point and SLL threshold are constant in all three cases, and SLL_{THR} is selected such that as V_{TPO} falls the SLL knee (SLL_{RP}) is greater than the DRC_{RP}.

In the first two cases (for V_{TPO1} and V_{TPO2}), the calculated SLL output voltage limit (V_{SLL}) is less than V_{TPO}. As the signal level increases, it is first compressed by the DRC function then limited once the output level reaches V_{SLL}. In the third case, the SLL function is never applied since V_{SLL} is greater than V_{TPO3} and the signal level, while still compressed by the DRC, reaches full-scale before exceeding V_{SLL}.

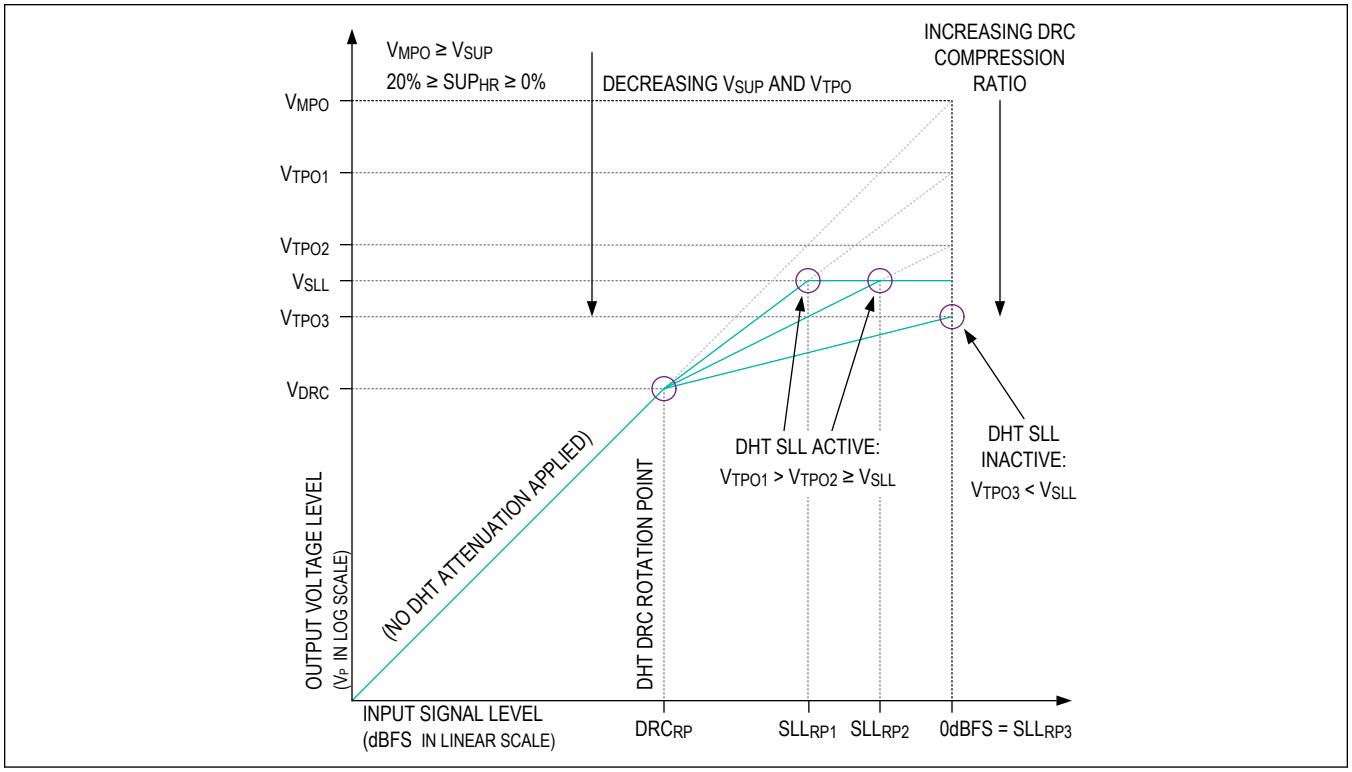

Figure 23. DHT DRC and SLL with Decreasing V_{SUP} (V_{TPO}), and SUP_{HR} ≥ 0%

Figure 24 shows a mode 4 transfer function where the supply headroom is negative (SUP_{HR} < 0%). As before, the SLL threshold (SLL_{THR}) is programmed so that the resulting SLL_{RP} is greater than the DRC_{RP}. This also insures that the resulting V_{SLL} is greater than V_{DRC} and less than V_{TPO}. As the audio signal level increases, it is first compressed by the DRC function, then limited once the digital output signal level reaches V_{SLL}. However, due to the negative headroom, the amplifier output clips before the SLL function digitally limits the signal level.

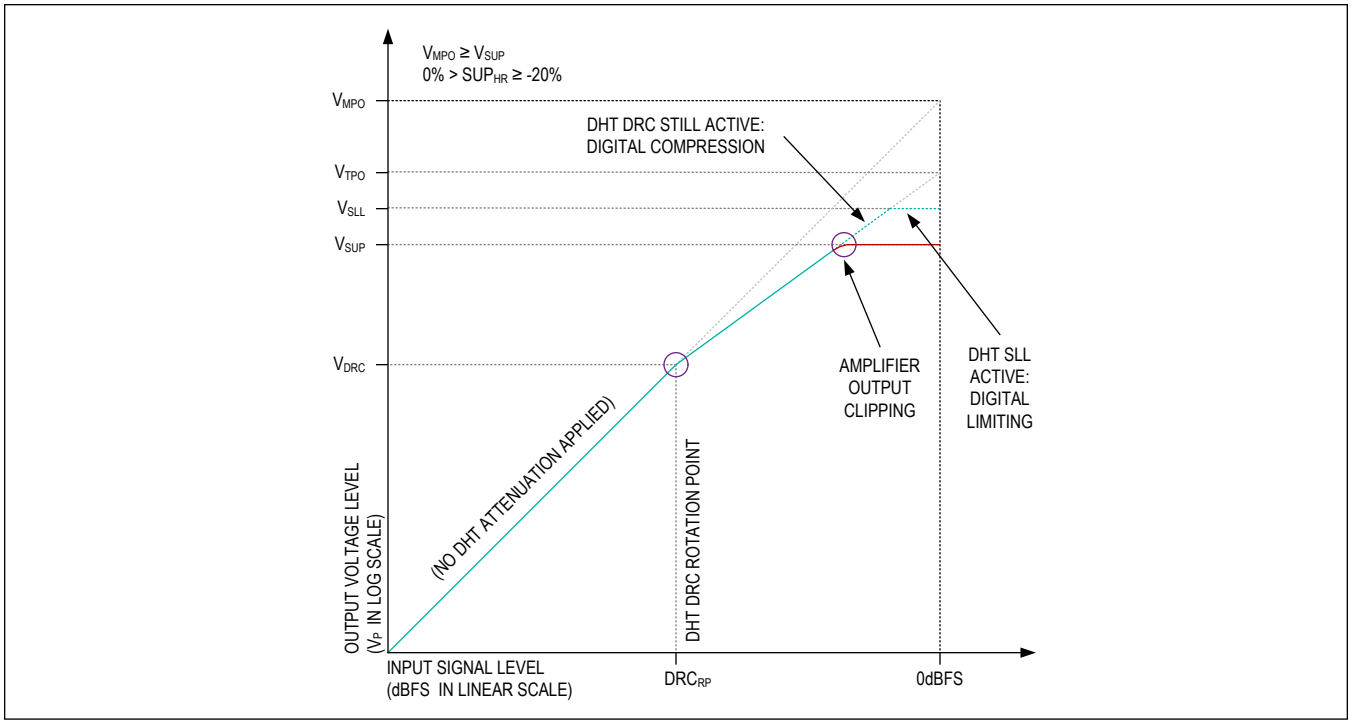

Figure 24. DHT DRC and SLL with Decreasing V_{SUP} (V_{TPO}), and SUP_{HR} < 0%

DHT Attenuation

An interrupt is generated (*DHT_ACTIVE_BGN_**) when the DHT block first applies attenuation. When the DHT block fully releases all applied attenuation (i.e., DHT is inactive), an interrupt is generated (*DHT_ACTIVE_END_**). Interrupts are not generated when DHT is actively adjusting the level of attenuation.

The maximum attenuation (A_{MAX}) applied to the audio signal by the DHT functions is selected with the *DHT_MAX_ATN* bit field. The maximum attenuation can be set from -1dB to -15dB with a 1dB step size. The configured DHT functions stop further attenuation of the audio signal once the calculated attenuation (relative to the un-attenuated input signal level) reaches the selected maximum attenuation (A_{MAX}). If the calculated attenuation (based on input signal level and measured V_{SUP}) exceeds the selected maximum attenuation (A_{MAX}), the applied attenuation is set equal to (limited at) A_{MAX}. This can occur anytime when the target peak output (V_{TPO}) to maximum peak output (V_{MPO}) ratio or peak output attenuation (denoted A_{TPO}) is less than (or has a larger absolute value than) A_{MAX}.

All previous examples show cases where the peak output attenuation (A_{TPO}) did not exceed the selected maximum attenuation (A_{MAX}). The following figures show signal distortion limiter use cases where V_{SUP} has decreased until A_{TPO} < A_{MAX} (the DHT DRC function DRC_{RP} is set to 0dbFS as in use case 1).

In Figure 25, the SUP_{HR} is set to -20%. Since A_{TPO} < A_{MAX}, the attenuation applied by the distortion limiter reaches the programmed maximum attenuation level before the input signal reaches full-scale. For input signals past the point where calculated attenuation is equal to A_{MAX}, the attenuation stops increasing and is now fixed at A_{MAX}. As a result, the audio signal (in the digital domain) begins to increase past this point. This results in the distortion increasing at the amplifier output (which was already clipping at the limited level of distortion).

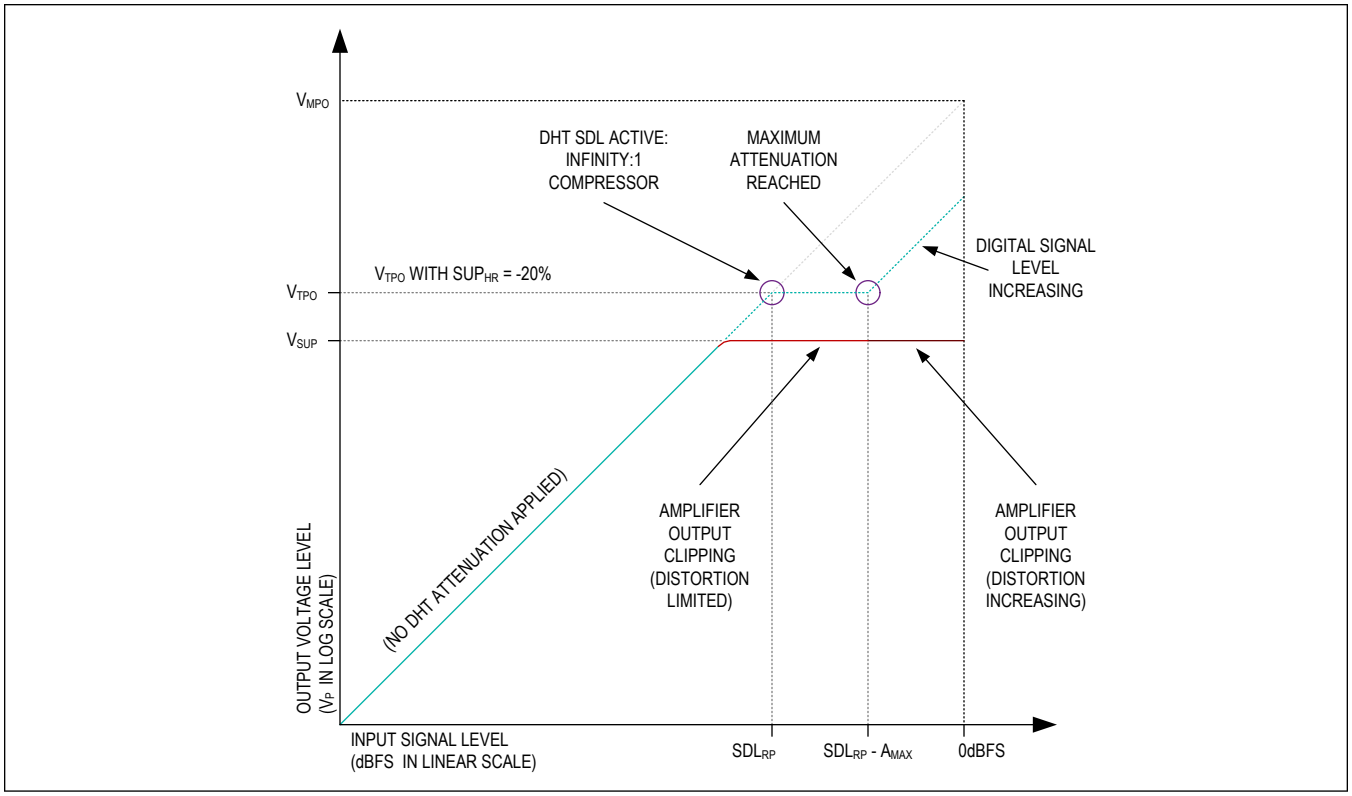

Figure 25. Distortion Limiter Case with -20% Headroom and A_{MAX} Exceeded

In Figure 26, the supply headroom is set to +20%. As before, the attenuation applied by the SDL reaches the selected maximum attenuation (A_{MAX}) before the input signal reaches full-scale. The audio signal (in the digital domain) begins increasing past this point, and the signal level (and any distortion) at the amplifier output increases as well. In this case, the amplifier output was not clipping until after A_{MAX} was exceeded.

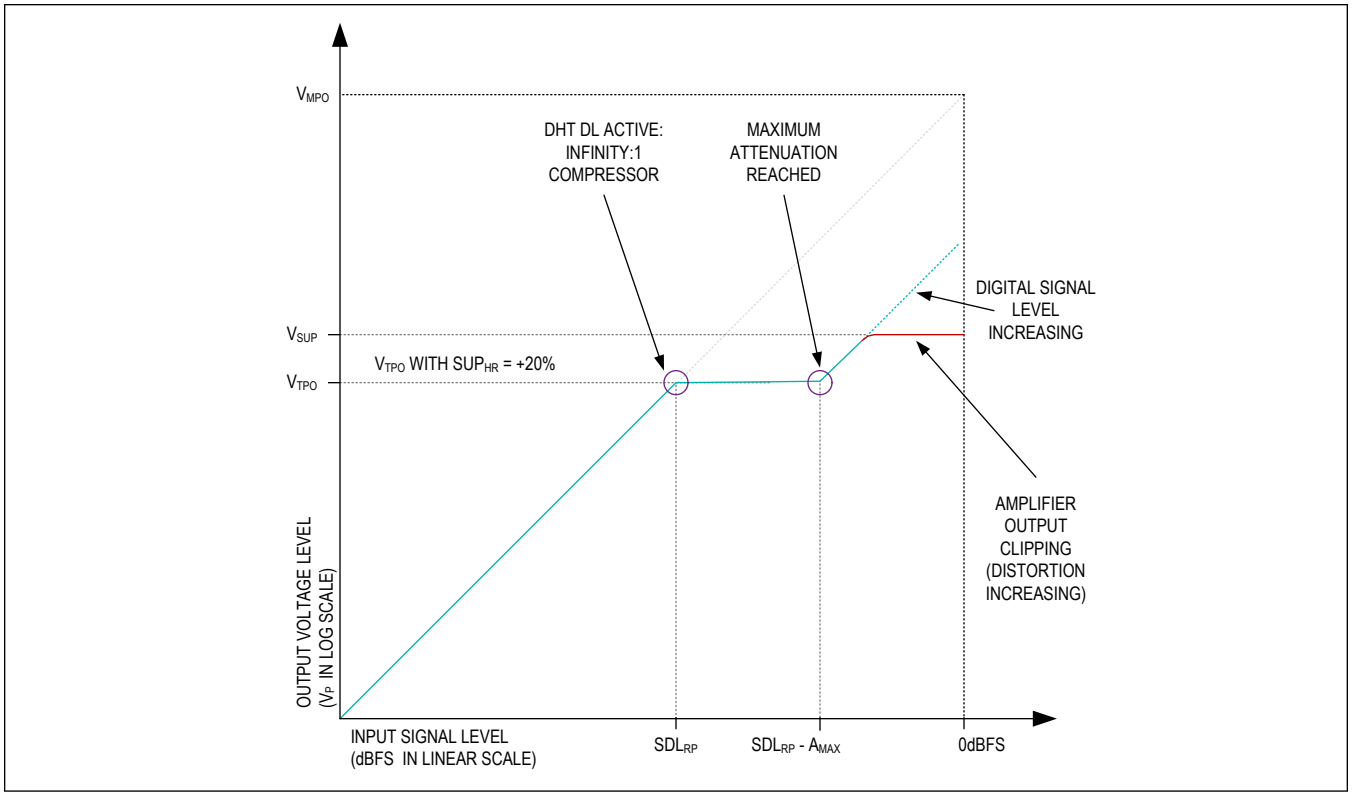

Figure 26. Distortion Limiter Case with +20% Headroom and A_{MAX} Exceeded

DHT Attenuation Reporting

In TDM mode, the current level of DHT attenuation is reported on the PCM data output (DOUT) when the DHT attenuation transmit enable bit is set high (*PCM_DHT_ATN_EN* = 1). The DHT attenuation level output is transmitted as a 14-bit unsigned binary attenuation level:

DOUT CURRENT DHT ATTENUATION (dB) = 20 x log(14-bit DOUT Value/16383)

If enabled, the DHT attenuation target (in dB) is also shared between devices on the interchip communication (ICC) bus. In this case, the DHT attenuation level output requires two ICC output slots (8 bits each) and is transmitted as a 10-bit unsigned binary attenuation level (DHT_ATN) followed by 6 bits of zero padding.

The current DHT attenuation (in dB) is calculated from the 10-bit value (DHT_ATN) with the following equation:

ICC CURRENT DHT ATTENUATION (dB) = - (DHT_ATN[9:0] x 0.015625dB)

The current DHT attenuation level cannot exceed the selected DHT maximum attenuation (A_{MAX}). Additionally, when the DHT is inactive, the reported attenuation is 0x0.

DHT Ballistics

When the signal level exceeds the rotation point or threshold for a configured DHT function (SDL, SLL, and/or DRC) or continues to increase beyond this point, the appropriate level of attenuation is applied to the signal level at the programmed attack rate. The DHT attack rate is selected with the *DHT_ATK_RATE* bit field.

The change in input signal level is detected by a peak detect circuit which has a fixed 3.5ms release time. When the signal level decreases or drops below the rotation point or threshold for a configured DHT function (SDL, SLL, and/or DRC), the appropriate level of applied attenuation is released. The DHT release rate is selected with the *DHT_RLS_RATE* bit field. However, due to the 3.5ms/dB peak detector, the 2ms/dB release rate is effectively 3.5ms/dB. All other release rates have a fixed delta of 3.5ms compared to the programmed release rate.

The attack and release behavior is slightly different when triggered by a change in active amplifier supply level. When the supply level decreases and triggers a DHT function attack, the attenuation is applied quickly at the configured attack rate. Likewise, as the supply level increases, the attenuation is released at the configured release rate. However, if DHT supply hysteresis is enabled (*DHT_SUPPLY_HYST_EN* = 1), then as the supply increases the applied DHT function does not release attenuation until the increase in the supply level exceeds the programmed DHT supply hysteresis level (*DHT_SUPPLY_HYST*). Once the supply increase exceeds the hysteresis, the appropriate level of applied attenuation is released at the configured release rate.

Speaker Amplifier

The device features a Class-DG speaker amplifier output stage. The speaker amplifier playback path is enabled and disabled using the *SPK_EN* bit. The Class-DG multilevel amplifier generates a rail-to-rail output, pulse-width modulated (PWM) signal. By varying the PWM duty cycle, the amplifier modulates the output with the audio input signal. Because the switching frequency of the amplifier is 472kHz (typ) when the output signal is filtered by the speaker, only the audio component remains. Rail-to-rail operation ensures that power dissipation at the output is dominated by the on resistance (R_{ON}) of the power output MOSFETs brief saturation current draw as the output switches as well as the current draw necessary to charge the output stage gates.

Speaker Amplifier Operating Modes

The speaker amplifier can operate both in Class-DG and standard Class-D modes. In Class-DG mode, the amplifier output supply rail is switched between V_{PVDD} and V_{VBAT} based on the signal level. If Class-DG operation is disabled, the amplifier operates as a fixed supply Class-D amplifier and can be configured to use either V_{PVDD} or V_{VBAT} as the output supply rail. The speaker amplifier operating mode is selected with the *SPK_MODE* bit field.

Class-DG Mode Enabled

Class-DG is the default speaker amplifier mode of operation (*SPK_MODE* = 0x0). In this mode, the amplifier switches the supply rail between PVDD and VBAT as needed to efficiently supply the required output power.

Additionally, if V_{VBAT} drops below the programmed threshold level *VBATLOW_OK_LVL* bit field, the amplifier operates from PVDD supply rail regardless of signal level.

The Class-DG signal level threshold (VDG_THR) at which the amplifier switches between the supply rails is programmable. The method used to program the signal level threshold is selected with the *SPK_DG_SEL* bit field. When *SPK_DG_SEL* is set to 0x0, the threshold (VDG_THR) is set to a fixed peak voltage level with the *SPK_DG_THRES* bit field. When *SPK_DG_SEL* is set to 0x1 (default), the threshold (VDG_THR) is variable relative to the current VBAT voltage (measurement ADC result). The peak voltage headroom relative to V_{VBAT} is configured with the *SPK_DG_HEADROOM* bit field. Finally, if *SPK_DG_SEL* is set to 0x2, the threshold (VDG_THR) is set based on whichever setting (*SPK_DG_THRES* or *SPK_DG_HEADROOM*) results in the lowest threshold for the current V_{VBAT} voltage level. As a result, as V_{VBAT} decreases, VDG_THR might transition from a fixed threshold to a lower V_{VBAT} headroom based variable threshold.

The Class-DG mode hold time is configured with the *SPK_DG_HOLD_TIME* bit field. VBAT is selected as the active amplifier supply to save power when the signal level drops below the threshold for longer than hold time. The amplifier switches to the VBAT supply only at signal zero cross, so the measured hold time is the register configured hold time plus the time taken for a zero cross event to occur. When VBAT is the active amplifier output supply, the LV_EN output asserts high. When the signal level rises above the threshold, the amplifier supply quickly switches to PVDD to provide higher output voltage swing and to avoid clipping. When PVDD is the active amplifier output supply, the LV_EN output asserts low.

Delay for DG Mode

When the amplifier is operating in the automatic Class-DG mode, to avoid the potential for clipping the output signal as the PVDD supply rises, there is a programmable delay in the signal path controlled by *SPK_DG_DELAY*. This allows the PVDD supply time to increase the output voltage before it is required to output larger signals.

Class-DG Mode Disabled

When Class-DG mode is disabled, the speaker amplifier operates in standard Class-D mode. In this case, the active amplifier output supply is configured to either PVDD (*SPK_MODE* = 0x1) or VBAT (*SPK_MODE* = 0x2).

If the active amplifier output supply is configured to VBAT (*SPK_MODE* = 0x2), the amplifier operates from VBAT regardless of signal level. In this mode, the LV_EN pin is asserted high.

When the active amplifier supply is set to PVDD, the amplifier always operates from PVDD regardless of the signal and supply levels. Furthermore, PVDD can be actively regulated between any levels within its standard operating range (3V to 20V) to save power. In this mode, LV_EN pin is always asserted low.

NOVBAT Mode

By default, the PVDD and VBAT pins must be supplied with external supplies for the amplifier to operate. In systems where the VBAT pin cannot be supplied by an external supply, the device can still operate from PVDD supply only by programming the *NOVBAT* bit field to 1. Additionally, the VBAT pin must be shorted to the VREFC pin on the PCB. When *NOVBAT* bit field is set to 1, the amplifier automatically operates in PVDD mode and the *SPK_MODE* bits have no effect.

IDLE Mode

In customer systems where an external LC filter is used for EMI reduction, the quiescent power consumption and power consumption in Class-DG mode for low signal levels can be reduced by setting the IDLE_MODE_EN bit field to 1. The idle mode setting is not intended for operation in PVDD mode (with VBAT pin supplied externally) or NOVBAT mode (when the VBAT pin is not supplied externally) and therefore should not be enabled.

When the idle mode is enabled, the idle mode activates whenever the amplitude of the input audio data to the speaker path (from the PCM interface) is below the configured mute threshold (*MUTE_THRESH*) for more than 1024 consecutive data samples. When the idle mode is active, the current and voltage sense ADC paths output zero code data. The idle mode deactivates immediately if the amplitude of a single sample from the input audio data exceeds the configured unmute threshold (*UNMUTE_THRESH*). When the idle mode deactivates, the current and voltage sense ADC paths resume operation and output data normally.

The idle mode mute and unmute threshold settings are selected in terms of the number of bits (starting from the LSB) that must be toggling (or active) in order for the input signal amplitude to exceed the thresholds. It is invalid to set the noise gate unmute threshold (*MUTE_THRESH*) such that it is less than the configured mute threshold (*MUTE_THRESH*). The location of the audio data LSB within the PCM input data channel is determined by the configured PCM data word size (*PCM_CHANSZ*). The supported combinations are shown in [[Noise Gate/Idle Mode Threshold LSB Location By Input Data Configuration]]. It is not valid to enable the idle mode and noise gate function simultaneously.

Speaker Amplifier Ultra-Low EMI Filterless Operation

Traditional Class-D amplifiers require the use of external LC filters or shielding to meet electromagnetic-interference (EMI) regulation standards. However, the device features emissions limiting circuitry that limits the output switching harmonics that can directly contribute to EMI and radiated emissions.

The programmable speaker amplifier edge rate control bits are used to adjust the switching edge rate to help tune EMI performance. As the edge rate increases, the efficiency improves slightly, while as the edge rate is decreased, the efficiency drops slightly. The speaker amplifier edge rate is configured with the *SPK_SL_RATE_GMODE*, *SPK_SL_RATE_LS*, and *SPK_SL_RATE_HS* bit fields.

The speaker amplifier output also supports spread-spectrum modulation (SSM). SSM is enabled by default to optimize the suppression and control of the output switching harmonics that can contribute to EMI and radiated emissions. The modulation index in spread-spectrum mode is controlled by the *SPK_SSM_MOD_INDEX* bit field, and the maximum modulation index (MMI) varies accordingly. Higher percentage settings of the modulation index result in the switching frequency of the amplifier being modulated by a wider range, spreading out-of-band energy across a wider bandwidth. Above 10MHz, the wideband spectrum looks like noise for EMI purposes.

Speaker Amplifier Overcurrent Protection

The device features amplifier current limit protection that protects the amplifier output from both high current and short circuit events. If the *OVC_AUTORESTART_EN* bit is set to 1 and the speaker amplifier output current exceeds the current limit threshold (6.2A min), the device generates an interrupt and disables the amplifier output. After approximately 20ms, the amplifier output is re-enabled. If the overcurrent condition still exists, the device continues to disable and re-enable the amplifier output automatically until the fault condition is removed.

If the *OVC_AUTORESTART_EN* bit is set to 0, the device still generates an interrupt and disables the amplifier output when a speaker amplifier overcurrent event occurs. However, in this case the device is placed into software shutdown and the software enable (*EN*) bit is set to 0. As a result, the host must manually re-enable the device after an overcurrent event.

Speaker Current and Voltage Sense ADC Path

The device provides two separate 16-bit ADCs to monitor the speaker amplifier output current and voltage (the I/V sense ADC path). The current and voltage ADC paths are independently enabled with the *IVADC_I_EN* and *IVADC_V_EN* bits, respectively.

The voltage and current digital data output are routed to the host through the PCM interface data output (DOUT), which is enabled by the PCM_TX_EN bit field. Both I and V data can be formatted in 16-/24-/32-bit 2's complement format and has a voltage sense range of ±22V, and a current sense range of ±6.5A.

When configured in 16-bit mode for Vsense, if MSB is 0 then the voltage would be 11/(2^15) x DIG CODE.

For example, a Vsense reading of 0111 1111 1111 1111 translates to a voltage of +22V and a reading of 1000 0000 0000 0000 would be -22V.

For 16-bit Isense, if MSB is 0, then the current would be 3/(2^15) x DIG CODE.

For example, an Isense reading of 0111 1111 1111 1111 translates to a voltage of +6.5A and a reading of 1000 0000 0000 0000 would be -6.5A.

See the *PCM Interface* section for details on configuring I/V sense-data output on DOUT. Both the current and voltage sense ADC output data can optionally have dither applied (±1 LSB peak-to-peak) by setting the *IVADC_DITH_EN* bit field to 1. No dither is applied when *IVADC_DITH_EN* is set to 0.

The I/V sense ADC path provides separate optional DC blocking filters (first-order highpass) in the current and voltage sense paths. The current and voltage path filters are enabled by setting the *IVADC_I_DCBLK_EN* and *IVADC_V_DCBLK_EN* bit fields to 1, respectively.

To ensure phase alignment, the current and voltage sense ADCs should be enabled either with a single write to the *IVADC_I_EN* and *IVADC_V_EN* bits (*EN* = 1) or by setting both bits high before exiting software shutdown. Additionally, all feedback channels (VMON, IMON, and *DSP feedback data*) are nominally in phase except for LRCLK sample rates of 88.2kHz/176.4kHz. For 88.2kHz/176.4kHz sample rates, VMON/IMON data is 180 degrees out of phase with the *DSP feedback data.*

When laying out the PCB, the OUTPSNS and OUTNSNS pins should be Kelvin connected as close as possible to the load connected between OUTP and OUTN for accurate voltage measurements. If a filter comprised of a ferrite bead and capacitor is installed between the speaker amplifier output pins and the load, then the sense lines should be connected between the filter and the load and as close to the load as possible. If an LC filter is installed between the amplifier output pins and the load, the OUTPSNS and OUTNSNS lines should be connected to the OUTP and OUTN lines before the filter. The OUTPSNS and OUTNSNS pins are not intended to be driven by an external source. The speaker amplifier current is measured internally and requires no external connections.

Brownout-Prevention Engine

The brownout-prevention engine (BPE) allows the device to reduce its contribution to the overall system power consumption by attenuating the amplifier output when the supply drops below a set of programmable thresholds. The BPE is enabled and disabled using the *BPE_EN* bit. The BPE can be enabled at any time by setting the *BPE_EN* bit

high. However, the BPE must not be disabled when it is active (in critical supply levels 0 through 3). The BPE can be disabled safely at any time that it is inactive. The input to the BPE controller is selected using the *BPE_SRC_SEL* bit. By default, the input to the BPE controller is the measurement ADC PVDD channel. If the selected measurement ADC channel is not already active, enabling the BPE will automatically enables it. The sample rate and filter settings for the measurement ADC determine the speed at which the BPE updates.

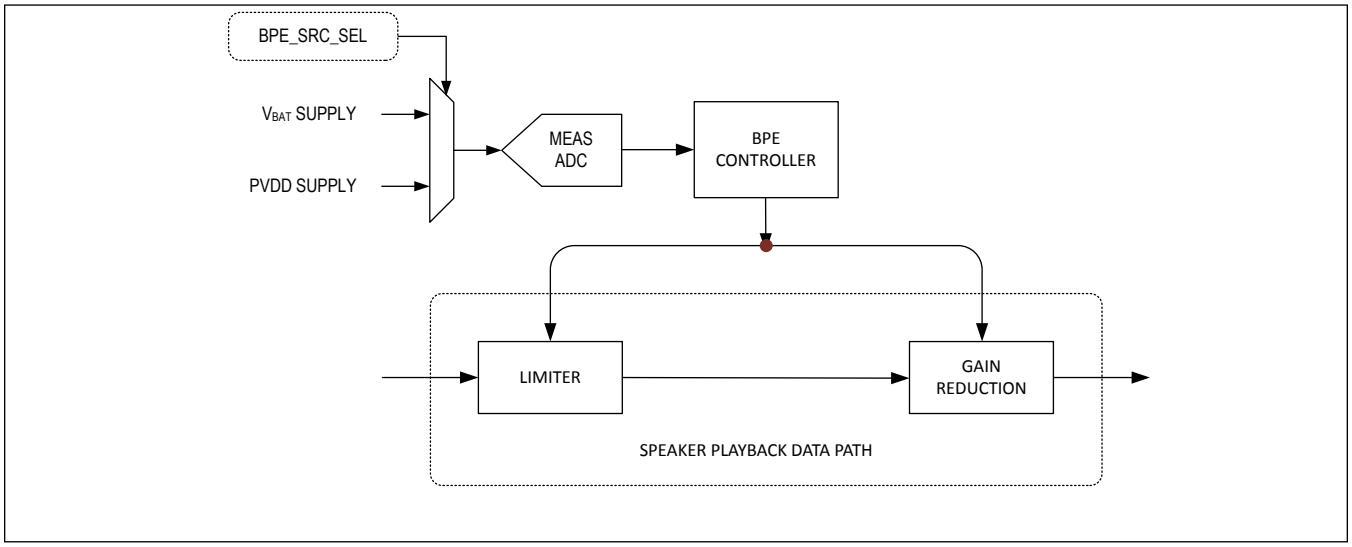

Figure 27. BPE Block Diagram

BPE State Controller and Level Thresholds

There are a total of four BPE critical supply levels, each with individually programmable thresholds. The thresholds for each level are configured with the *BPE_L0_VTHRESH* to *BPE_L3_VTHRESH* bit fields respectively. The BPE state controller monitors the measurement ADC channel results and automatically makes state changes.

Table 9. Brownout-Prevention Engine Levels

THRESHOLD NAME	CONDITION
BPE Inactive	VSUPPLY > Critical Supply Level 3
Critical Supply Level 3	Critical Supply 3 ≥ VSUPPLY > Critical Supply Level 2 + Hysteresis
Critical Supply Level 2	Critical Supply Level 2 ≥ VSUPPLY > Critical Supply Level 1 + Hysteresis
Critical Supply Level 1	Critical Supply Level 1 ≥ VSUPPLY > Critical Supply Level 0 + Hysteresis
Critical Supply Level 0	VSUPPLY ≤ Critical Supply Level 0

The brownout engine supports hysteresis on the levels. This behaves as follows:

- When in level N, transition to level N + 1 when V_{SUPPLY} stays above (level N threshold) + (hysteresis)
- When in level N, transition to level N - 1 when V_{SUPPLY} falls below level N threshold

The amount of hysteresis is defined by the *BPE_VTHRESH_HYST* register. The hysteresis is only applied to the thresholds when supply voltage is increasing. The amount of hysteresis can be defined as larger than the distance between two levels.

Thresholds must be configured so that the level N threshold is greater than the sum of the level N - 1 threshold and the hysteresis. For example, if the level 2 threshold is set to 3.15V and hysteresis is set to 25mV, then the level 3 threshold must be set to 3.1875V or higher.

The current level that the BPE is in can be read-back using the *BPE_STATE* register. The *BPE_LOWEST* register contains the lowest BPE level that the controller has visited since the last time the *BPE_LOWEST* register was read.

BPE Level Configuration Options

For a given BPE level, the following options are configurable to reduce the overall device current draw:

Gain Attenuation Function

Limiter Function

Each of these configuration options are individually configurable for each BPE level.

BPE Gain Attenuation Function

The speaker gain attenuation block reduces the overall current draw by the device at low supply voltages by applying smooth digital gain changes to the signal path. The maximum attenuation that can be applied can be independently configured for each BPE level. The maximum attenuation that can be applied for each level is programmable from 0 to -31dB in 1dB steps and is configured using the *BPE_Lx_MAXATTN* bits.

When the V_{SUPPLY} voltage level falls below the programmed level, the brownout controller waits for a time equal to the programmed dwell time for the level before applying attenuation at the programmed attack rate. The brownout controller then enters the hold time phase when the V_{SUPPLY} voltage increases and causes the brownout controller to enter the next level. After the programmed hold time for a BPE level expires, the controller enters the release phase where the controller releases the attenuation at the programmed release rate. Additionally, each BPE level has independent programmable settings for dwell time (*BPE_Lx_DWELL*), hold time (*BPE_Lx_HOLD*), attack and release step size (*BPE_Lx_STEP*), attack rate (*BPE_Lx_GAIN_ATK*), and release rate (*BPE_Lx_GAIN_RLS*). While the attack and release rates are independently configurable for the gain attenuation and limiter block, the attack and release step size settings are common.

The *BPE_LOWEST_GAIN* register contains the lowest gain (highest attenuation) applied the brownout controller. The register is updated upon reading to show the current attenuation applied by the BPE.

BPE Limiter Function

The BPE limiter function allows the device to reduce the overall current draw at low supply levels by quickly attenuating (15µs) input signals that exceed a programmed threshold. When the BPE limiter is enabled (*BPE_LIM_EN* = 1), the device ignores the Signal Distortion Limiter and Signal Level Limiter settings in the DHT. In this state, the limiter knee threshold is determined solely by the BPE limiter setting of the current BPE level. Each BPE level has an individually configured limiter threshold (set by *BPE_Ln_LIM*) that is programmable from 0dBFS and -15dBFS in 1dB steps.

Input signals that exceed the limiter knee threshold are attenuated, while input signals below the threshold are not. Each BPE level has an individually configured attack and release step size (*BPE_Lx_STEP*), attack rates (*BPE_Lx_LIM_ATK*), and release rates (*BPE_Lx_LIM_RLS*). While the attack and release rates are independently configurable for the gain attenuation and limiter block, the attack and release step size settings are common.

The *BPE_LOWEST_LIMIT* register contains the lowest limiter setting applied the brownout controller. The register is updated upon reading to show the current limiter setting applied by the BPE.

Brownout Interrupts

The BPE can generate interrupts triggered by the following conditions:

- BPE controller enters level 0 (*BPE_L0_**)
- BPE controller changes from one level to another (*BPE_LEVEL_**)
- BPE controller is active (*BPE_ACTIVE_BGN_**)
- BPE controller is no longer active (*BPE_ACTIVE_END_**)

See the *Interrupts* section for more information.

Measurement ADC

The device features a configurable 9-bit measurement ADC. The measurement ADC has three channels, one for die temperature measurement (measurement ADC thermal channel), one for PVDD supply voltage measurement (measurement ADC PVDD channel), and one for VBAT supply voltage measurement (measurement ADC VBAT channel). Enabled channels are measured sequentially and continuously. The programmable measurement ADC sample rate can be set independently for each channels. Each channel separately provides an optional programmable lowpass IIR filter.

Measurement ADC Thermal Channel

When the device is clocked in the active state (EN = 1), the measurement ADC thermal channel automatically activates. When active, it continuously measures and reports the device die temperature over the range from -29°C to +150°C.

The output of the thermal ADC channel can be readback through the *MEAS_ADC_THERM_DATA* bit field and is the input to both the thermal protection and thermal foldback blocks. By default (*MEAS_ADC_THERM_RD_MODE* = 0), the thermal readback value is automatically updated after each conversion is completed. Setting *MEAS_ADC_THERM_RD_MODE* to 1 places thermal readback into manual mode. In manual mode, the thermal readback result is updated manually when 1 is written to the *MEAS_ADC_THERM_UPD* bit field. The ADC thermal channel data readback in manual mode and the data streamed through the PCM interface are 9 bits. In automatic mode, since the 9-bit data readback is from two registers, the LSB register is not guaranteed to be synchronous with the MSB register and can result in higher noise.

The thermal ADC channel also provides an optional lowpass IIR filter with a programmable bandwidth that scales relative to the measurement ADC sample rate. The filter is enabled with the *MEAS_ADC_TEMP_FILT_EN* bit field, and the bandwidth is set with the *MEAS_ADC_TEMP_FILT_COEFF* bit field.

Measurement ADC PVDD Channel

When the device is clocked and in the active state (*EN* = 1), the measurement ADC PVDD channel can be enabled. The PVDD channel is manually enabled by setting the MEAS_ADC_PVDD_EN bit to 1 and must be manually enabled for the DHT to operate. When the channel is enabled, it continuously measures and reports the PVDD supply voltage level over the range of 2.5V to 20V.

The output of the measurement ADC PVDD channel can be read back through the *MEAS_ADC_PVDD_DATA* bit field and is routed to the DHT. By default (*MEAS_ADC_PVDD_RD_MODE* = 0), the PVDD readback value is automatically updated after each conversion is completed. Setting *MEAS_ADC_PVDD_RD_MODE* to 1 places PVDD readback into manual mode. In manual mode, the readback result is updated when 1 is written to the *MEAS_ADC_PVDD_RD_UPD* bit field. The ADC PVDD channel data readback in manual mode and the data streamed through the PCM interface are 9 bits. In automatic mode, since the 9-bit data readback is from two registers, the LSB register is not guaranteed to be synchronous with the MSB register and can result in higher noise.

The lowest PVDD measurement is readback through the *LOWEST_PVDD_DATA_MSB* and *LOWEST_PVDD_DATA_LSB* bit fields. These bit fields both automatically clear and are reset to the value of the current measurement result immediately after LSB readback is completed.

The PVDD channel also provides an optional lowpass IIR filter with a programmable bandwidth that scales relative to the measurement ADC sample rate. The filter is enabled with the *MEAS_ADC_PVDD_FILT_EN* bit and the bandwidth is set with the *MEAS_ADC_PVDD_FILT_COEFF* bit field.

Measurement ADC VBAT Channel

When the device is clocked in the active state (EN = 1), the measurement ADC VBAT channel can be enabled. The VBAT channel is manually enabled by setting the *MEAS_ADC_VBAT_EN* bit to 1 and must be manually enabled for the DHT to operate. When the channel is enabled, it continuously measures and reports the VBAT supply voltage level over the range of 2.5V to 5.5V.

The output of the measurement ADC VBAT channel can be read back through the *MEAS_ADC_VBAT_DATA* bit field. By default (*MEAS_ADC_VBAT_RD_MODE* = 0), the VBAT readback value is automatically updated after each conversion

is completed. Setting *MEAS_ADC_VBAT_RD_MODE* to 1 places VBAT readback into manual mode. In manual mode, the readback result is updated when 1 is written to the *MEAS_ADC_VBAT_RD_UPD* bit field. The ADC VBAT channel data readback in manual mode and the data streamed through the PCM interface are 9 bits. In automatic mode, since the 9-bit data readback is from two registers, the LSB register is not guaranteed to be synchronous with the MSB register and can result in higher noise.

The lowest measured VBAT measurement result is readback through the *LOWEST_VBAT_DATA_MSB* and *LOWEST_VBAT_DATA_LSB* bit fields. These bit fields both automatically clear and are reset to the value of the current measurement result immediately after LSB readback is completed.

The VBAT channel also provides an optional lowpass IIR filter with a programmable bandwidth that scales relative to the measurement ADC sample rate. The filter is enabled with the *MEAS_ADC_VBAT_FILT_EN* bit and the bandwidth is set with the *MEAS_ADC_VBAT_FILT_COEFF* bit field.

Clock and Data Monitors

The device has input data and external clock monitors that detect host and system level faults. The data monitor detects persistent stuck and high amplitude input signals while the clock monitor detects external clock failures and invalid clock configurations. Upon fault detection, these monitors automatically place the device into software shutdown to stop glitches and unwanted signals at the amplifier output and speaker load.

Input Data Monitor

The device has an optional input data monitor that is enabled by setting *DMON_MAG_EN* to 1 for the data magnitude monitor or *DMON_STUCK_EN* to 1 (for the data stuck monitor). Once the data monitor is enabled, it actively monitors the selected input data (from DIN) to the speaker amplifier path anytime the device exits software shutdown (*EN* = 1) and the amplifier is enabled (*SPK_EN* = 1). When the tone generator is enabled, the data monitor is automatically disabled.

When active, the block monitors the selected input data for the enabled data error types (data magnitude, data stuck, or both). The *DMON_DURATION* bit field selects the duration that a data stuck or magnitude error must persist before a data error is detected. Once a data error is detected, the data monitor automatically places the device into software shutdown (sets EN to 0) and generates a data monitor error interrupt (*DMON_ERR_**).

A data stuck error is detected if the input signal repeats a fixed value with a magnitude (positive or negative) that is beyond the data stuck threshold (*DMON_STUCK_THRES*) for longer than the data error duration (set by *DMON_DURATION*). If the input signal repeats a fixed value for any duration with a magnitude that is within the data stuck threshold limits (such as a zero or near zero code), no data stuck error is detected.

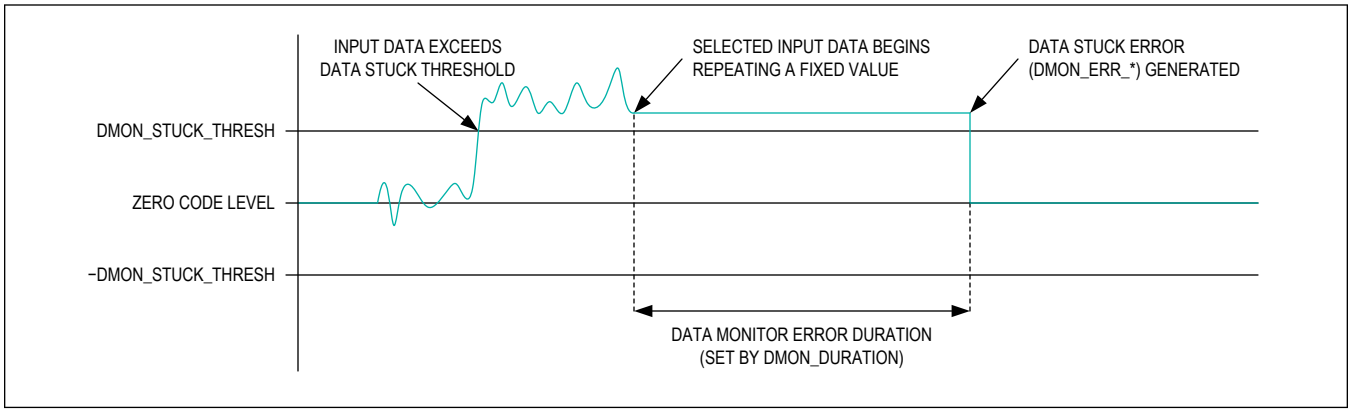

Figure 28. Data Monitor Error Generation due to Input Data Stuck Error Detection

A data magnitude error is detected if the input signal magnitude (positive or negative) is beyond the data magnitude threshold (set by *DMON_MAG_THRES*) for longer than the data error duration (set by *DMON_DURATION*).

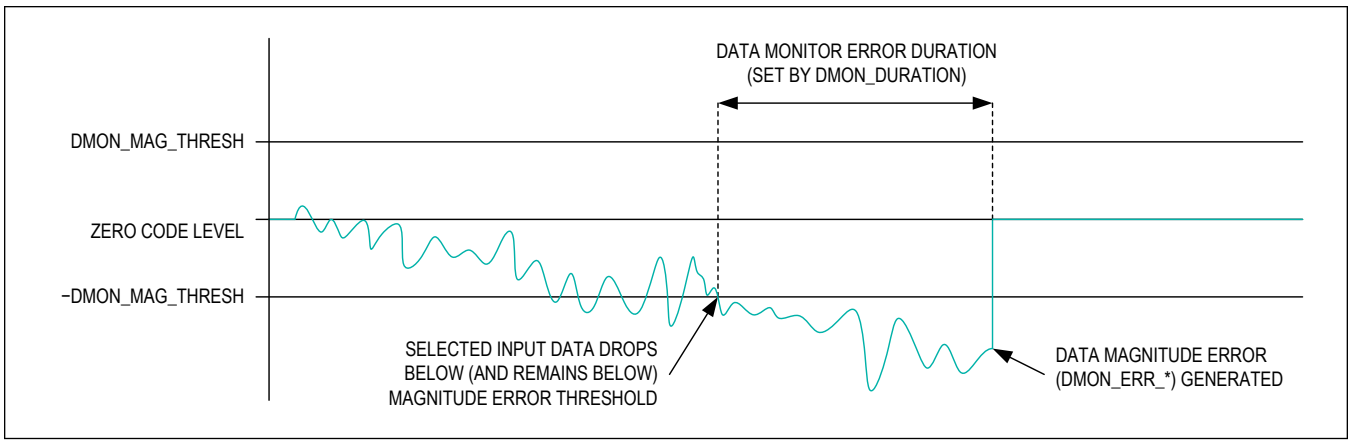

Figure 29. Monitor Error Generation due to Input Data Magnitude Error Detection

Clock Monitor

The device provides an optional clock monitor that is enabled by setting *CMON_EN* to 1. Once enabled, it actively monitors the input BCLK and LRCLK anytime the device exits software shutdown (*EN* = 1). When the tone generator is enabled, the clock monitor is automatically disabled. When active, the clock monitor detects clock activity, clock frequency, and frame timing (clock ratio). If faults are detected, the clock monitor automatically places the device into software shutdown and generates a clock error interrupt (*CLK_ERR_**).

The clock monitor operates in automatic mode when *CMON_AUTORESTART_EN* = 1 and manual mode when *CMON_AUTORESTART_EN* = 0. In automatic mode, when a clock error places the device into software shutdown, the global enable bit (EN) is not changed (remains 1) and the device automatically recovers from all clock errors. In automatic mode, both clock error (*CLK_ERR_**) and clock recovery (*CLK_RECOVER_**) interrupts are generated in pairs (a clock recovery interrupt is not possible until after a clock error has occurred).

In manual mode, when a clock error places the device into software shutdown, the global enable bit (*EN*) is set to 0. Clock recovery (*CLK_RECOVER_**) interrupts are never generated in manual mode, and the device remains in software shutdown until the host sets *EN* back to 1. Once the device is re-enabled (*EN* set to 1), the clock monitor is active and detects any new (or persisting) clock errors. If a clock error is detected, the device returns to software shutdown (*EN* = 0), and a new clock error interrupt (*CLK_ERR_**) is generated.

Clock errors are fault conditions, and audible glitches may occur on clock monitor based transitions into and out of software shutdown. When the clock monitor is enabled, no false clock error or clock recovery interrupts are generated when the host software transitions the device normally into and out of software shutdown.

Clock Activity and Frequency Detection

When the clock monitor is enabled, the bit clock (BCLK) and frame clock (LRCLK) frequencies are monitored. The expected LRCLK frequency is equal to the PCM sample rate (*PCM_SR*). The expected BCLK frequency is based on the BCLK to LRCLK ratio (*PCM_BSEL*) relative to the PCM sample rate (*PCM_SR*).

The current frequency of each clock is measured relative to (and once per interval of) the programmed frame period (as set by *PCM_SR*). A clock frequency error is detected when the measured clock frequencies differ from programmed clock frequencies (faster or slower) by more than the frequency error threshold (45% typ). If either clock stops high or low, the frequency measurement result allows detection of the clock stop event.

The *CMON_ERRTOL* bit field sets the clock frequency error tolerance. The tolerance is the required number of consecutive frame clock periods (*PCM_SR*) with an incorrect clock frequency before a clock error is generated. If the error persists for the selected number of frame periods, a clock error interrupt (*CLK_ERR_**) is generated and the device is placed into software shutdown.

In automatic mode, the *CMON_ERRTOL* bit field also sets the number of consecutive frame clock periods without clock frequency errors (LRCLK or BCLK) that are required for automatic restart to occur. Once the selected number of

consecutive error-free frames are detected, a clock recovery interrupt (*CLK_RECOVER_**) is generated and the device automatically exits software shutdown.

In manual mode, no clock recovery interrupts are generated. The clock monitor remains disabled and the device remains in software shutdown until the host software sets *EN* back to 1.

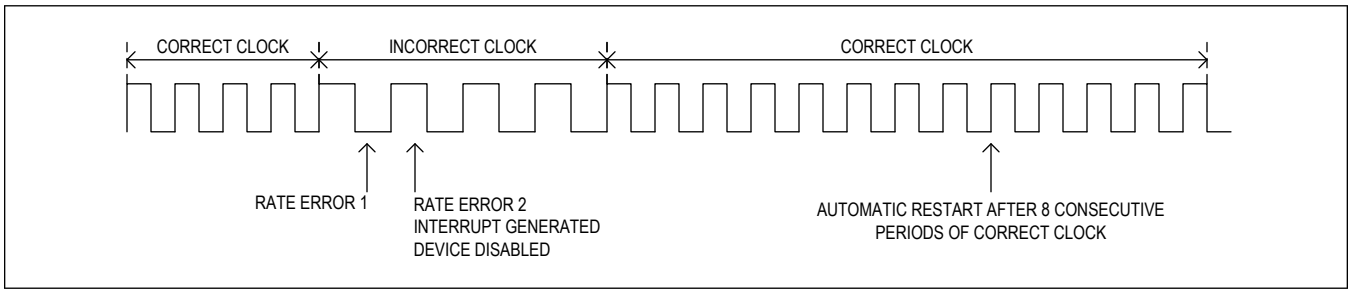

Figure 30. Clock Monitor LRCLK Rate Error Example With CMON_ERRTOL = 0x1

Clock Frame Error Detection

When the clock monitor is enabled, the bit clock (BCLK) to frame clock (LRCLK) ratio is monitored. The clock monitor counts the number of BCLK periods per frame (LRCLK period) and then compares the count to the configured clock ratio (*PCM_BSEL*). In addition, in I^2S and left-justified modes the clock monitor verifies the LRCLK duty cycle by checking that the number of BCLK periods per channel is equal. In TDM mode, data transport is synchronized to the active frame clock (LRCLK) edge, so no duty cycle restrictions are enforced.

A frame error is detected in each frame where the monitored clock ratio (and duty cycle in I^2S and left-justified modes) differs from the configured settings. The *CMON_BSELTOL* bit field sets the number of consecutive frames with frame errors that are required before a clock error interrupt is generated (*CLK_ERR_**) and the device is placed into software shutdown.

In automatic mode, the *CMON_BSELTOL* bit field also sets the number of consecutive frames without frame errors that are required for automatic restart to occur. Once the selected number of consecutive error-free frames are detected, a clock recover interrupt (*CLK_RECOVER_**) is generated and the device automatically exits software shutdown.

In manual mode, no clock recovery interrupts are generated; the clock monitor remains disabled and the device remains in software shutdown until the host software sets *EN* back to 1.

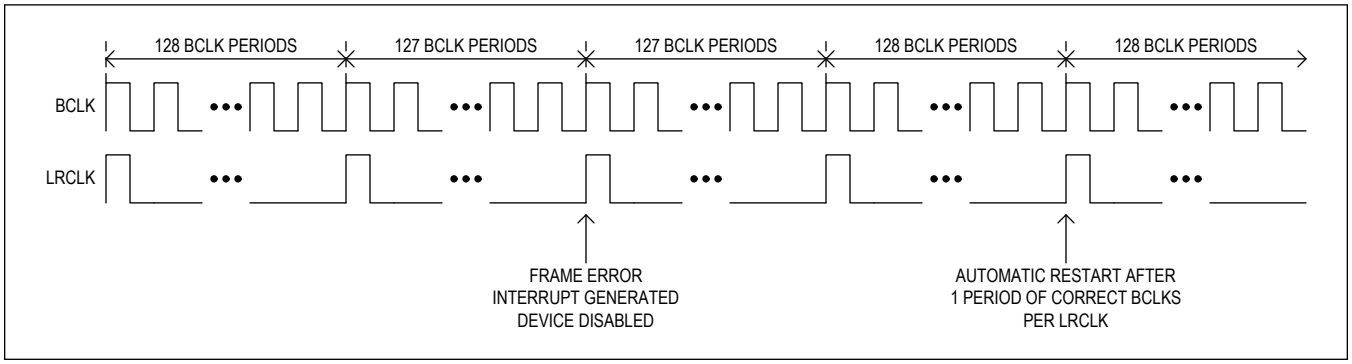

Figure 31. Clock Monitor Framing Error Example In TDM Mode With PCM_BSEL = 0x6 and CMON_BSELTOL = 0x0

Speaker Monitor

The speaker monitor is a circuit that is designed to protect the speaker against amplifier signals that could damage it. The speaker monitor is enabled by default and can be disabled by setting the *SPKMON_EN* bit to zero. The circuit monitors the amplifier's PWM signal and shuts down the amplifier output when the signal goes above a programmed speaker

monitor threshold (set by SPKMON_THRESH) for a programmed amount of time (set by SPKMON_DURATION). Additionally, the device also generates an INT_SPKMON_ERR interrupt.

The speaker monitor circuit uses PWM signals of the amplifier, and in the case of DC signals, the amplifier accurately detects signals above the threshold. However, for a sine wave with a DC offset, the average DC detected by the circuit is lower because of the zeroes presented from the sine signal. In this case, the speaker monitor threshold (set by SPKMON_THRESH) and/or the speaker monitor duration (set by SPKMON_DURATION) can be adjusted to protect the speaker against the DC present in the signal.

Thermal Protection

When the device is active, the measurement ADC thermal channel is automatically enabled and monitors die temperature to ensure that it does not exceed the configured thermal thresholds. Interrupt registers are provided so that the device can notify the host when the die temperature crosses either the thermal warning or thermal-shutdown threshold, or when thermal foldback starts and stops.

Thermal Warning and Thermal Shutdown Configuration

The device features two thermal-warning thresholds. The thermal-warning thresholds are configured by THERMWARN1_THRESH[6:0] and THERMWARN2_THRESH[6:0] bit fields and the thermal shutdown threshold is configured by the THERMSHDN_THRESH[5:0] bit field. The thermal-warning2 threshold should always be set to a temperature higher than or equal to thermal-warning1 temperature. Additionally, the thermal-warning2 threshold temperature should never be configured higher than the thermal shutdown threshold temperature minus hysteresis. When the die temperature is decreasing, hysteresis is applied to thermal-shutdown, thermal-warning1, and thermal-warning2 thresholds. The temperature hysteresis is configured with THERM_HYST bit field.

Thermal Shutdown Recovery Configuration

The device thermal-shutdown recovery behavior is determined by the state of THERM_AUTORESTART_EN bit. When the THERM_AUTORESTART_EN bit is set to 0, the thermal-shutdown recovery is in manual mode. In manual mode, when the die temperature exceeds the thermal shutdown threshold, an interrupt is generated and the amplifier output is automatically disabled. Once the die temperature drops below both of the thermal-shutdown threshold minus the hysteresis and the thermal-warning2 threshold minus the hysteresis, the appropriate interrupts are generated to notify the host. In addition, once the die temperature drops below the thermal-warning2 threshold minus the hysteresis, the device is placed into software shutdown (EN is set to 0) and remains in that state until the host manually re-enables the device. When the THERM_AUTORESTART_EN bit is set to 1, the thermal-shutdown recovery is in automatic mode. In automatic mode, when the die temperature exceeds the thermal-shutdown threshold, an interrupt is generated and the amplifier is automatically disabled. Once the die temperature drops below the thermal shutdown threshold minus the hysteresis, an interrupt is generated but the amplifier remains disabled. When the temperature drops below the thermal-warning2 threshold minus the hysteresis, another interrupt is generated and (unlike manual mode) the amplifier is then automatically re-enabled.

Thermal Foldback

The device features thermal foldback to allow for a smoother audio response to high temperature events. Thermal foldback is enabled by setting the THERMFB_EN bit to 1. The device provides two thermal-warning thresholds that are configured by the THERMWARN1_THRESH[6:0] and THERMWARN2_THRESH[6:0] bit fields. They should be set such that thermal-warning2 threshold temperature is higher than or equal to thermal-warning1 threshold temperature. Additionally, the thermal-warning2 threshold temperature should never be configured higher than the thermal shutdown threshold temperature minus hysteresis.

Once enabled, thermal foldback begins when the die temperature exceeds the configured thermal-warning1 threshold, interrupts are generated (THERMFB_BGN_* and THERMWARN1_BGN_*), and attenuation is applied to the speaker amplifier path. The slope of the thermal foldback attenuation is programmed with the THERMFB_SLOPE1 bit field.

If the die temperature continues to increase and exceeds the configured thermal-warning2 threshold, an interrupt (THERMWARN2_BGN_*) is generated and attenuation continues to be applied to the speaker amplifier path. The slope of the attenuation applied to the speaker amplifier path is programmed with the THERMFB_SLOPE2 bit field. As the die

temperature increases, the level of attenuation also increases proportionally up to a maximum level of -12dB (unless the thermal shutdown threshold is exceeded first). When thermal foldback is active, the attack time for a gain change can be a maximum of two samples. Additionally, there is a sample delay in the signal path attenuation due to the group delay of the amplifier.

When the die temperature starts to decrease and drops below the thermal-warning2 threshold minus the programmed hysteresis level and remains there for longer than the programmed hold time (set with the *THERMFB_HOLD* bit field), the attenuation starts to release and an interrupt (*THERMWARN2_END_**) is generated. If the die temperature continues to reduce and drops below the thermal-warning1 threshold temperature minus the programmed hysteresis level, thermal foldback ends and interrupts (*THERMFB_END_** and *THERMWARN1_END_**) are generated. The attenuation release rate (for decreasing temperature) is programmable and configured with the *THERMFB_RLS* bit field.

Tone Generator

The device includes a tone generator which is enabled using the *TONE_EN* bit field and replaces the PCM interface as the input source to the speaker playback path. When the tone generator is enabled, both it and the speaker playback path operate without the need for any external clocks.

The tone generator output is configured to generate sine wave or DC tones (using the *TONE_CONFIG* bit field).

The tone generator can create sine waves with either a 1kHz fixed frequency or a variable sample rate dependent frequency. When a sample rate based sinewave output is selected, the tone generator output frequency is set by the playback sample rate setting (*PCM_SR*) divided by the selected ratio (as set by *TONE_CONFIG*). For the playback sample rate of 44.1kHz and its multiples, the tone generator output frequency can vary by up to 9%. The tone generator supports all available sample rate settings (*PCM_SR*). The amplitude of the output sine wave relative to full-scale is selected with the *TONE_AMPLITUDE* bit field.

The tone generator can output either a fixed or a programmable DC output level (as set by *TONE_CONFIG*). Fixed DC output levels of zero code, positive half-scale, and negative half-scale are provided for quick configuration. If the programmable DC output level is selected (*TONE_CONFIG*), the DC level is configured as a signed two's complement value with the *TONE_DC* bit field.

Pink Noise Generator

The device includes a pink noise generator, which is enabled using the PINK_NOISE_EN bit field and replaces the PCM interface as the input source to the speaker playback path. The pink noise generator and the tone generator cannot be enabled at the same time. When the pink noise generator is enabled, both it and the speaker playback path operate without the need for any external clocks. The output level of the generator is fixed, so the amplifier gain and speaker volume must be used to adjust the level.

Interchip Communication

The device features an interchip communication (ICC) interface that uses a shared data bus to facilitate synchronized speaker amplifier path attenuation adjustments across groups of devices. Depending on the configuration, the ICC interface can synchronize brownout-prevention engine (BPE), DHT, and thermal foldback. Each device receives the data of the other grouped devices and reacts accordingly.

ICC Operation and Data Format

The bidirectional ICC bus is used to synchronize the responses of grouped devices. To create the ICC bus, the ICC interface pins of each device are externally connected together (whether or not the devices are in the same group). The ICC bus operates with the same clock sources and data format configuration as the PCM interface data input (DIN), and can support a maximum of 16 channels. For a given valid PCM interface configuration, the number of available ICC data channels per frame is calculated as follows (based on the *PCM_CHANSZ*, *PCM_BSEL*, and *PCM_FORMAT* settings):

Number of Available Data Input Channels = BCLK to LRCLK Ratio / Channel Length

The ICC interface is disabled when both the ICC data transmit output (*ICC_TX_EN*) and the ICC data link (*ICC_LINK_EN*) are disabled. To enable the ICC interface, both *ICC_TX_EN* and *ICC_LINK_EN* must be set to

1. It is invalid to set these controls to different values, and both must always be set to the same state (either enabled or disabled). Once the ICC link and data transmit are enabled, the ICC data output channel is assigned with the *ICC_TX_DEST* bit field. The ICC pin is Hi-Z during all other data channels, and can be configured (with the *ICC_RX_CHn_EN* bits) to accept data from the output data channels of grouped devices.

The transmitted ICC data is always the same size as the configured PCM data input word size (set by *PCM_CHANSZ*). When a 16-bit data word is selected, the ICC data word is not long enough to synchronize BPE, DHT, and thermal foldback. In this case, the *ICC_DATA_SEL* bit is used to choose whether the DHT function or thermal foldback function is synchronized in addition to BPE state. When a 24-bit or 32-bit data word size is selected, ICC can synchronize BPE, DHT, and thermal foldback across a given group. In these cases, the *ICC_DATA_SEL* bit has no effect. Active ICC data channels always contain ICC data words followed by zero padding bit up to the ICC data channel length (which is equal to PCM input data channel length). If BPE, DHT, or thermal foldback is disabled for any given group, then the transmitted ICC data for the disabled function(s) is always zero code.

Multiamplifier Grouping

The ICC interface allows multiple devices to be grouped so that BPE, DHT, and thermal foldback behavior can be synchronized. The receive channel enables (*ICC_RX_CHn_EN*) are used to define groups. A given device monitors all selected channels (when *ICC_RX_CHn_EN* = 1, and n denotes the channel number) on the ICC data bus. The configured set of receive channels must also include the assigned transmit channel (as set by *ICC_TX_DEST*) for any given device. Each device in a given group must have identical settings for all ICC receive channel enables (*ICC_RX_CHn_EN*). Furthermore, all devices in the same group must have identical DHT, thermal protection, and thermal foldback settings to achieve a synchronized response across the group. The behavior of a group as a whole is undefined if any given device in a group has different settings.

The ICC bus can support a maximum of 16 data channels. The minimum size of a group is two devices, and as a result the maximum number of concurrent groups on a single ICC bus is eight. A group can contain as many as 16 devices, but then only a single group is possible on a single ICC bus.

ICC Multi-Group Example

Consider a system design that includes four devices that require DHT synchronization, and that two distinct groups of two devices each (with different DHT settings) must share single ICC bus. The PCM interface (and thus ICC bus) is configured in TDM mode 1 with four 16-bit data channels available. One possible configuration (among many) is to assign devices 1 and 3 to the first group (denoted group A), and to assign devices 2 and 4 to the second group (denoted group B).

To configure group A, both devices 1 and 3 are set to monitor channels 0 and 2 by programming *ICC_RX_CH0_EN* = 1 and *ICC_RX_CH2_EN* = 1 on both devices (all other ICC receive bit fields are 0). Device 1 transmits on channel 0 (*ICC_TX_DEST* = 0x0) and device 3 transmits on channel 2 (*ICC_TX_DEST* = 0x2).

To configure group B, both devices 2 and 4 are set to monitor channels 1 and 3 by programming *ICC_RX_CH1_EN* = 1 and *ICC_RX_CH3_EN* = 1 on both devices (all other ICC receive bit fields are 0). Device 2 transmits on channel 1 (*ICC_TX_DEST*= 0x1) and device 4 transmits on channel 3 (*ICC_TX_DEST* = 0x3).

Since the ICC channel length and data word size is limited to 16 bits, the *ICC_DATA_SEL* bit field in all four devices must be set to 0 to select DHT target attenuation synchronization. Finally, on all four devices set *ICC_LINK_EN* = 1 and *ICC_TX_EN* = 1 to enable the ICC interfaces.

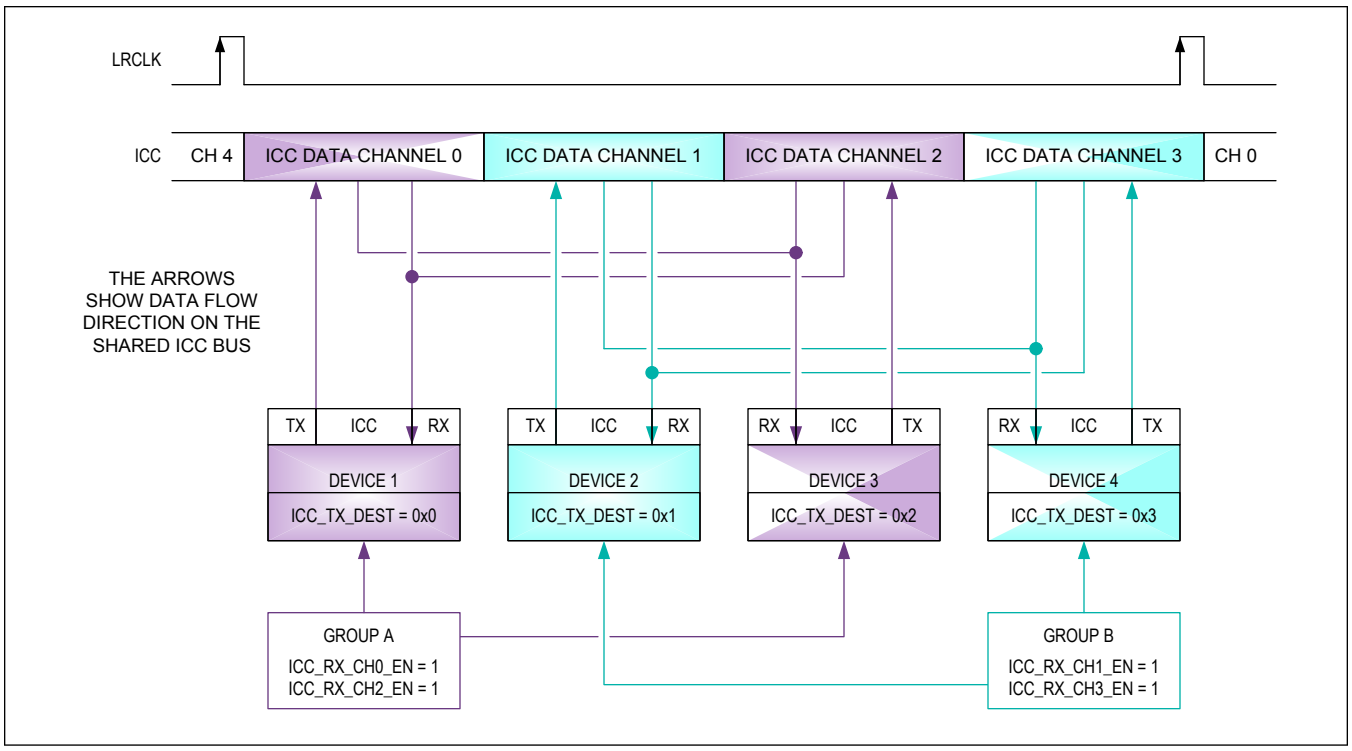

Figure 32. ICC Multi-Group Example with 2 Groups and 4 Total Devices

I²C Serial Interface

The I²C serial control interface is activated when the device detects a valid I²C start condition at the I2C1 and I2C2 pins. The I2C1 and I2C2 pins can each act as either SCL or SDA respectively, and the start condition configures the device address and state of each pin. After the first I²C transaction, the I²C interface configuration should remain fixed.

Slave Address

The slave address is defined as the seven most significant bits (MSBs) followed by the read/write bit. The seven most significant bits are programmable through the ADDR connection, and the required I2C1 and I2C2 connections for each address are shown in Table 10. The device does not communicate if ADDR is floating. Setting the read/write bit to 1 configures the device for read mode. Setting the read/write bit to 0 configures the device for write mode. The address is the first byte of information sent to the IC after the START condition.

Table 10. I²C Slave Address

I2C1	I2C2	ADDR CONNECTION	I²C SLAVE ADDRESS (BINARY)	I²C WRITE ADDRESS (BINARY)	I²C READ ADDRESS (BINARY)
SDA	SCL	Connected to DVDDIO	0111000x	01110000	01110001
SDA	SCL	Connected to GND	0111001x	01110010	01110011
SDA	SCL	Connected to SDA	0111010x	01110100	01110101
SDA	SCL	Connected to SCL	0111011x	01110110	01110111
SCL	SDA	Connected to DVDDIO	0111100x	01111000	01111001
SCL	SDA	Connected to GND	0111101x	01111010	01111011
SCL	SDA	Connected to SDA	0111110x	01111100	01111101
SCL	SDA	Connected to SCL	0111111x	01111110	01111111

The IC features an I2C/SMBus™-compatible, 2-wire serial interface consisting of a serial data line (SDA) and a serial clock line (SCL). SDA and SCL facilitate communication between the IC and the master at clock rates up to 1MHz. Figure 33 shows the 2-wire interface timing diagram. The master generates SCL and initiates data transfer on the bus. The master device writes data to the IC by transmitting the proper slave address followed by two register address bytes (most significant byte first) and then the data word. Each transmit sequence is framed by a START (S) or REPEATED START (Sr) condition and a STOP (P) condition. Each word transmitted to the IC is 8 bits long and is followed by an acknowledge clock pulse. A master reading data from the IC transmits the proper slave address followed by a series of nine SCL pulses. The IC transmits data on SDA in sync with the master-generated SCL pulses. The master acknowledges receipt of each byte of data. Each read sequence is framed by a START (S) or REPEATED START (Sr) condition, a not acknowledge, and a STOP (P) condition. SDA operates as both an input and an open-drain output. A pullup resistor, typically greater than 500Ω, is required on SDA. SCL operates only as an input. A pullup resistor, typically greater than 500Ω, is required on SCL if there are multiple masters on the bus, or if the single master has an open-drain SCL output. Series resistors in line with SDA and SCL are optional. Series resistors protect the digital inputs of the IC from high voltage spikes on the bus lines, and minimize crosstalk and undershoot of the bus signals.

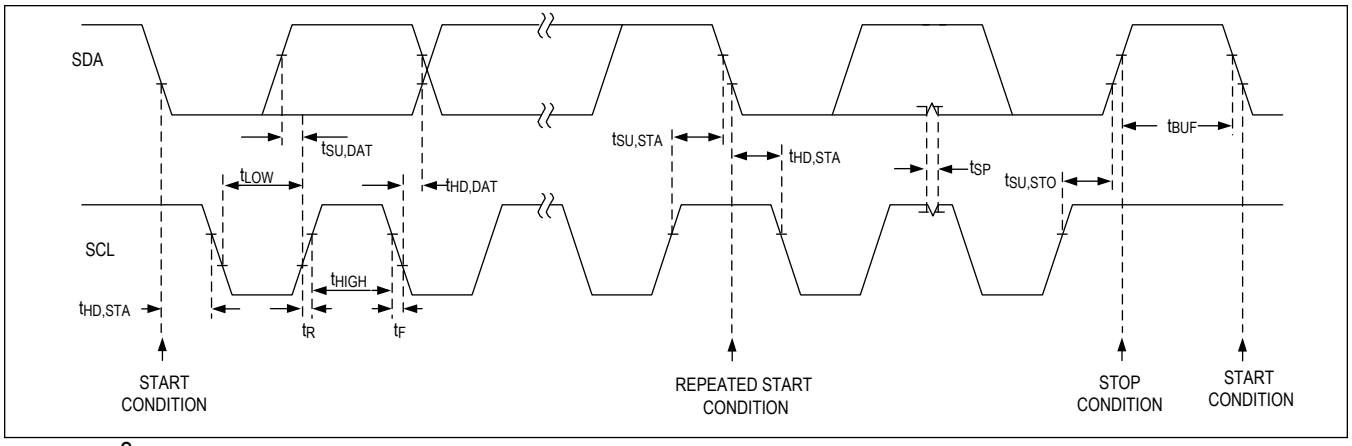

Figure 33. I2C Interface Timing Diagram

Bit Transfer

One data bit is transferred during each SCL cycle. The data on SDA must remain stable during the high period of the SCL pulse. Changes in SDA while SCL is high are control signals (see the *START and STOP Conditions* section).

START and STOP Conditions

SDA and SCL idle high when the bus is not in use. A master initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA while SCL is high. A START condition from the master signals the beginning of a transmission to the IC. The master terminates transmission and frees the bus by issuing a STOP condition. The bus remains active if a REPEATED START condition is generated instead of a STOP condition.

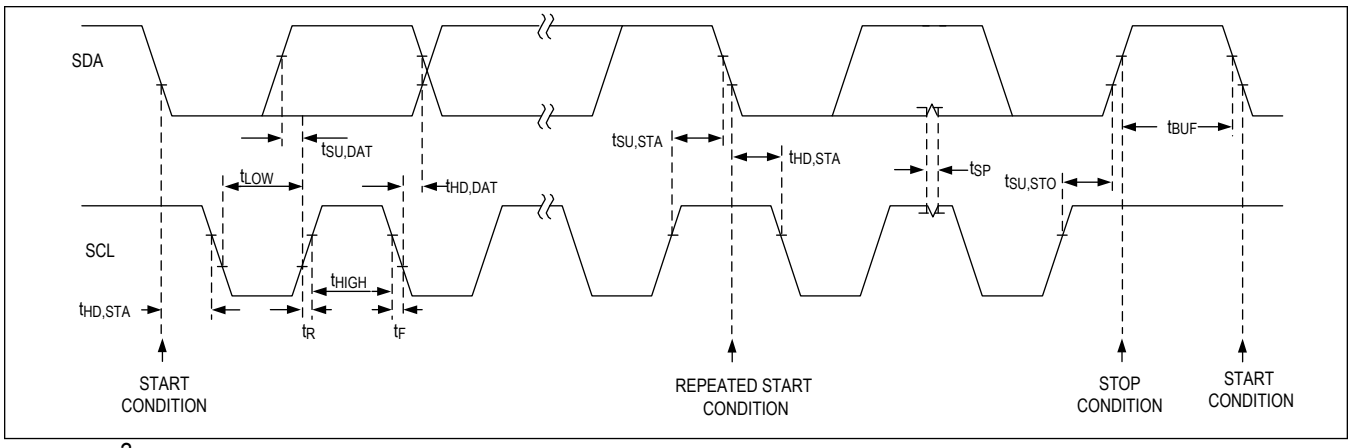

Figure 34. I²C START, STOP, and REPEATED START Conditions

Early STOP Conditions

The IC recognizes a STOP condition at any point during data transmission except if the STOP condition occurs in the same high pulse as a START condition. For proper operation, do not send a STOP condition during the same SCL high pulse as the START condition.

Acknowledge

The acknowledge bit (ACK) is a clocked 9th bit that the IC uses to handshake receipt each byte of data when in write mode. The IC pulls down SDA during the entire master-generated 9th clock pulse if the previous byte is successfully received. Monitoring ACK allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master retries communication. The master pulls down SDA during the 9th clock cycle to acknowledge receipt of data when the IC is in read mode. An acknowledge is sent by the master after each read byte to allow data transfer to continue. A not-acknowledge is sent when the master reads the final byte of data from the IC, followed by a STOP condition.

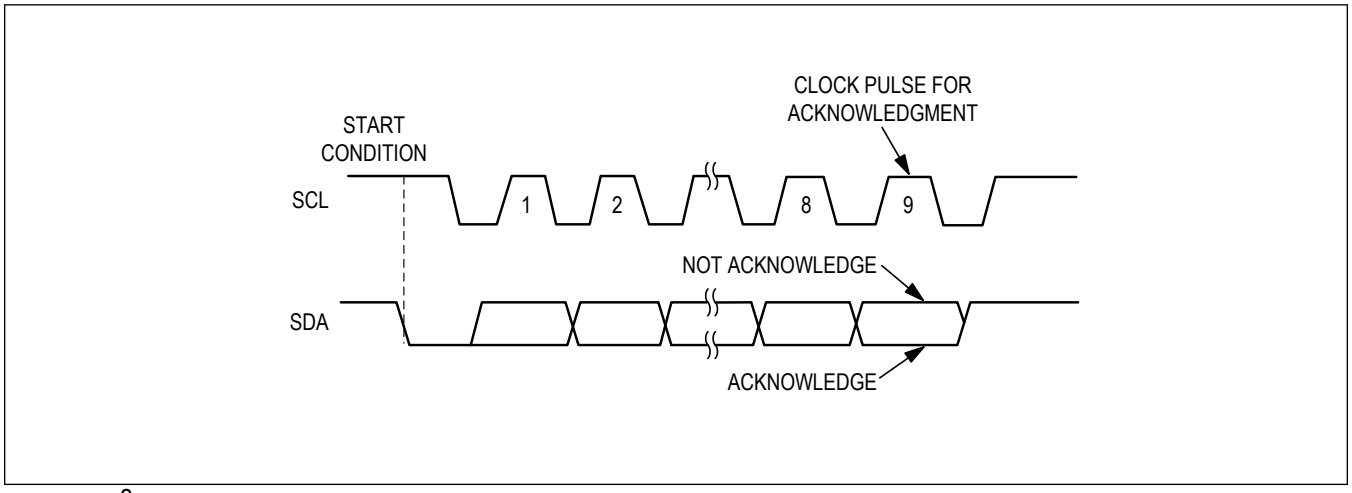

Figure 35. I²C Acknowledge

Write Data Format

A write to the IC includes transmission of a START condition, the slave address with the R/W bit set to 0, two bytes of data to configure the internal register address pointer, one or more bytes of data, and a STOP condition.

The slave address with the R/W bit set to 0 indicates that the master intends to write data to the IC. The IC acknowledges receipt of the address byte during the master-generated 9th SCL pulse.

The second and third bytes transmitted from the master configure the ICs internal register address pointer. The pointer tells the IC where to write the next byte of data. An acknowledge pulse is sent by the IC upon receipt of the address pointer data.

The third byte sent to the IC contains the data that is written to the chosen register. An acknowledge pulse from the IC signals receipt of the data byte. The address pointer auto-increments to the next register address after each received data byte. This auto-increment feature allows the master to write to sequential registers within one continuous frame. The master signals the end of transmission by issuing a STOP condition.

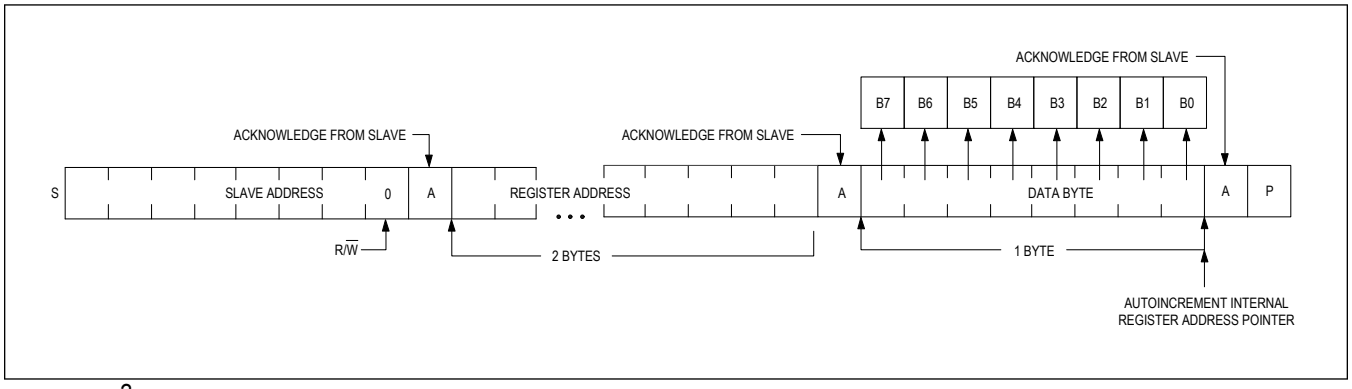

Figure 36. I²C Writing One Byte of Data to the Slave

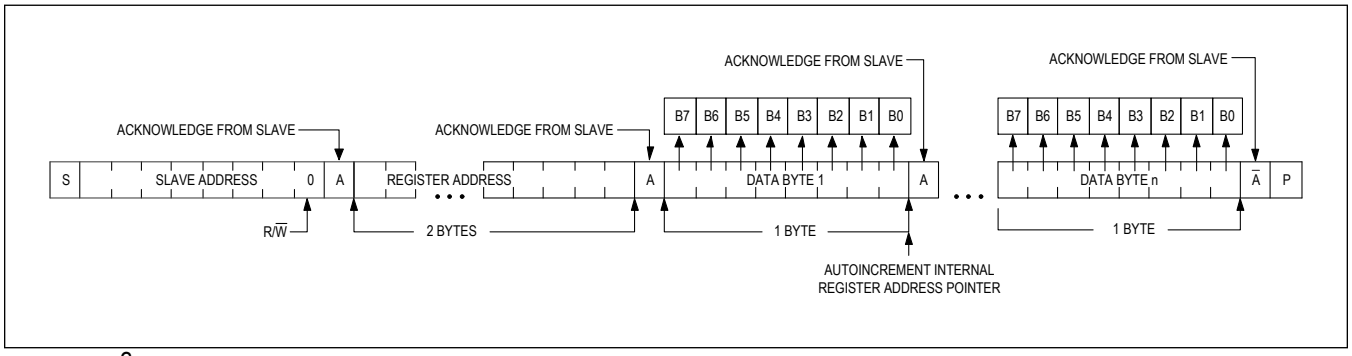

Figure 37. I²C Writing n-Bytes of Data to the Slave

Read Data Format

Initiate a read operation by sending the slave address with the R/W bit set to 1. The IC acknowledges receipt of its slave address by pulling SDA low during the 9th SCL clock pulse. A START command followed by a read command resets the address pointer to register 0x2000.

The first byte transmitted from the IC is the content of register 0x00. Transmitted data is valid on the rising edge of SCL. The address pointer auto-increments after each read data byte. This auto-increment feature allows all registers to be read sequentially within one continuous frame. A STOP condition can be issued after any number of read data bytes. If a STOP condition is issued followed by another read operation, the first data byte to be read is from register 0x00.

The address pointer can be preset to a specific register before a read command is issued. The master presets the address pointer by first sending the ICs slave address with the R/W bit set to 0 followed by the two byte register address. A REPEATED START condition is then sent followed by the slave address with the R/W bit set to 1. The IC then transmits the contents of the specified register. The address pointer auto-increments after transmitting the first byte.

The master acknowledges receipt of each read byte during the acknowledge clock pulse. The master must acknowledge

all correctly received bytes except the last byte. The final byte must be followed by a not acknowledge from the master and then a STOP condition.

I²C Register Map

Control Bit Field Types and Write Access Restrictions

The device control bit fields fall into one of three basic types: read, write, or read and write. There are no read restrictions, and any read enabled bit field can be read back anytime the I²C control interface is active. However, there are write restrictions, and every write enabled bit field falls into one of two write access subtypes.

The first write access subtype is dynamic. Dynamic bit fields effectively have no write access restrictions, and can be safely changed (written) in any device state where the I²C control interface is active. The second bit field access subtype is restricted. Restricted bit fields should only be changed (written) when the related functional block (as shown in Table 11) is powered down.

If the write access is restricted to the global enable (restrictions EN and ENL), then the restricted bit field should only be changed (written) when the device is in software-shutdown. As a form of system protection, write access to some critical global enable restricted bit fields (ENL) is locked out by the hardware when the device is not in the software-shutdown state. Attempting to change (write to) these locked restricted bit fields when the device is not in the software-shutdown state has no effect (read access is still allowed).

The bit field type and write access subtype is provided for every bit field in the detailed register description tables. For all bit fields with the restricted subtype, the dependency is also denoted in the "RES" column.

Table 11 provides a detailed description of all device register types, access subtypes, and restriction dependencies that are used by this device. The write access restrictions describe the specific device condition(s) that should be met (and the corresponding bit field settings) before the system attempts to change (write to) bit fields with that restriction type.

Table 11. Control Bit Types and Write Access Restrictions

BIT FIELD TYPE	WRITE ACCESS	WRITE ACCESS RESTRICTIONS		"RES" SYMBOL
		DESCRIPTION	CONDITION	

Table 11. Control Bit Types and Write Access Restrictions (continued)

Read	Read Only	—	—	—
Write or Read/ Write	Dynamic	—	—	—
	Restricted	Device in Software Shutdown	EN = 0	**EN**
		Write Access Locked Out by Hardware Unless the Device in Software Shutdown	EN = 0	**ENL**
		Speaker Amplifier Output and Feedback Disabled	SPK_EN = 0 and SPK_FB_EN = 0	**SPK**
		Voltage and Current Sense ADCs Disabled	IVADC_V_EN = 0 and IVADC_I_EN = 0	**IVS**
		Thermal Foldback Disabled	THERMFB_EN = 0	**TFB**
		Noise Gate Disabled	NOISEGATE_EN = 0	**NG**
		Dynamic-Headroom Tracking Disabled	DHT_EN = 0	**DHT**
		Brownout-Prevention Engine Disabled	BPE_EN = 0	**BPE**
		PCM Interface Data Input and Output Disabled	PCM_RX_EN = 0 and PCM_TX_EN = 0	**PCM**
		PCM Data Output Disabled	PCM_TX_EN = 0	**TXEN**
		IRQ Bus Output Disabled	IRQ_EN = 0	**IRQ**
		Interchip Communication (ICC) Interface Disabled	ICC_LINK_EN = 0 and ICC_TX_EN = 0	**ICC**

Register Details

Software Reset (0x2000)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	RST
Reset	–	–	–	–	–	–	–	0b0
Access Type	–	–	–	–	–	–	–	Write Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
RST	0	–	This bit field is used to trigger a software reset event. Writing a 1 resets the device and returns the control registers to their power-on reset states. Writing a 0 has no effect, and readback always returns 0.	0: No action 1: Triggers a software reset event

Interrupt Raw 1 (0x2001)

BIT	7	6	5	4	3	2	1	0
Field	THERMSHDN_BGN_RAW	THERMSHDN_END_RAW	THERMWARN1_BGN_RAW	THERMWARN1_END_RAW	THERMFB_BGN_RAW	THERMFB_END_RAW	OTP_FAIL_RAW	SPK_OVC_RAW
Reset	0b0	0b0	0b0	0b0	0b0	0b0	0b0	0b0
Access Type	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMSHDN_BGN_RAW	7	–	Raw value of thermal shutdown begin indicator	0: Die temperature below thermal shutdown limit 1: Die temperature above thermal shutdown limit

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMSHDN_END_RAW	6	–	Raw value of thermal shutdown end indicator	0: Die temperature above thermal shutdown limit 1: Die temperature has dropped below thermal shutdown limit
THERMWARN1_BGN_RAW	5	–	Raw value of thermal-warning1 begin indicator	0: Die temperature below thermal-warning1 limit 1: Die temperature above thermal-warning1 limit
THERMWARN1_END_RAW	4	–	Raw value of thermal-warning1 end indicator	0: Die temperature above thermal-warning1 limit 1: Die temperature has dropped below thermal-warning1 limit
THERMFB_BGN_RAW	3	–	Raw value of thermal foldback begin	0: Thermal foldback is not active 1: Thermal foldback is active
THERMFB_END_RAW	2	–	Raw value of thermal foldback end	0: Thermal foldback is active 1: Thermal foldback has ended
OTP_FAIL_RAW	1	–	Raw status of OTP load fail	0: No OTP load failure 1: OTP load routine did not complete succesfully
SPK_OVC_RAW	0	–	Raw value of speaker overcurrent limit	0: Speaker overcurrent limit inactive 1: Speaker overcurrent limit active

Interrupt Raw 2 (0x2002)

BIT	7	6	5	4	3	2	1	0
Field	THERMWARN2_BGN_RAW	THERMWARN2_END_RAW	INT_SPKMON_ERR_RAW	INT_CLK_ERR_RAW	–	CLK_RECOVER_RAW	CLK_ERR_RAW	DMON_ERR_RAW
Reset	0b0	0b0	0b0	0x0	–	0x0	0x0	0b0
Access Type	Read Only	Read Only	Read Only	Read Only	–	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMWARN2_BGN_RAW	7	–	Raw value of thermal-warning2 begin indicator	0: Die temperature below thermal-warning2 limit 1: Die temperature above thermal-warning2 limit
THERMWARN2_END_RAW	6	–	Raw value of thermal-warning2 end indicator	0: Die temperature above thermal-warning2 limit 1: Die temperature has dropped below thermal-warning2 limit
INT_SPKMON_ERR_RAW	5	–	Raw value of the internal speaker monitor status indicator	0: Internal speaker monitor not reporting data error 1: Internal speaker monitor reporting data error
INT_CLK_ERR_RAW	4	–	Raw value of internal clock error indicator	0: Internal clock monitor not reporting clock error 1: Internal clock monitor reporting clock error

BITFIELD	BITS	RES	DESCRIPTION	DECODE
CLK_RECOVER_RAW	2	–	Raw value of the external clock monitor error recovery indicator	0: Clock monitor not reporting clock error recovery 1: Clock monitor reporting clock error recovery
CLK_ERR_RAW	1	–	Raw value of the external clock monitor error indicator	0: No external clock error detected 1: Clock monitor reporting clock error
DMON_ERR_RAW	0	–	Raw value of external data monitor error indicator	0: No external data error detected 1: Data monitor reporting data error

Interrupt Raw 3 (0x2003)

BIT	7	6	5	4	3	2	1	0
Field	–	–	PWRUP_DONE_RAW	PWRDN_DONE_RAW	PVDD_UVLO_SHDN_RAW	VBAT_UVLO_SHDN_RAW	DHT_ACTIVE_BGN_RAW	DHT_ACTIVE_END_RAW
Reset	–	–	0b0	0b0	0b0	0b0	0b0	0b0
Access Type	–	–	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
PWRUP_DONE_RAW	5	–	Raw value of power-up done	0: Device is not reporting a power-up event 1: Device is reporting a power-up into the active state with the speaker amplifier enabled
PWRDN_DONE_RAW	4	–	Raw value of power-down done	0: Device is not reporting a power-down into software shutdown event 1: Device is reporting a power-down into software shutdown event
PVDD_UVLO_SHDN_RAW	3	–	Raw value of PVDD UVLO error indicator	0: No PVDD UVLO error 1: PVDD below UVLO threshold in the active state
VBAT_UVLO_SHDN_RAW	2	–	Raw value of VBAT UVLO error indicator	0: No VBAT UVLO error 1: VBAT below UVLO threshold in the active state
DHT_ACTIVE_BGN_RAW	1	–	Raw value of DHT active begin	0: DHT is not active 1: DHT is active
DHT_ACTIVE_END_RAW	0	–	Raw value of DHT active end	0: DHT is currently active or has not yet applied attenuation 1: DHT activity has ended

Interrupt Raw 4 (0x2004)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	BPE_L0_RAW	BPE_LEVEL_RAW	BPE_ACTIVE_BGN_RAW	BPE_ACTIVE_END_RAW
Reset	–	–	–	–	0x0	0x0	0x0	0x0
Access Type	–	–	–	–	Read Only	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_L0_RAW	3	–	Indicates that BPE has transitioned into level 0	0: BPE controller is not in level 0 1: BPE controller has transitioned into level 0
BPE_LEVEL_RAW	2	–	Indicates that BPE has transitioned between levels	0: BPE is static 1: BPE level is changing
BPE_ACTIVE_BGN_RAW	1	–	Indicates that the BPE is active	0: BPE is inactive 1: BPE is active
BPE_ACTIVE_END_RAW	0	–	Indicates that the BPE is no longer active	0: BPE is active 1: BPE is inactive

Interrupt State 1 (0x2006)

BIT	7	6	5	4	3	2	1	0
Field	THERMSHDN_BGN_STATE	THERMSHDN_END_STATE	THERMWARN1_BGN_STATE	THERMWARN1_END_STATE	THERMFB_BGN_STATE	THERMFB_END_STATE	OTP_FAIL_STATE	SPK_OVC_STATE
Reset	0b0	0b0	0b0	0b0	0b0	0b0	0b0	0b0
Access Type	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMSHDN_BGN_STATE	7	–	Unmaskable interrupt state, cleared by THERMSHDN_BGN_CLR.	0: No rising edge of THERMSHDN_BGN_RAW since last THERMSHDN_BGN_CLR 1: Rising edge of THERMSHDN_BGN_RAW since last THERMSHDN_BGN_CLR
THERMSHDN_END_STATE	6	–	Unmaskable interrupt state, cleared by THERMSHDN_END_CLR.	0: No rising edge of THERMSHDN_END_RAW since last THERMSHDN_END_CLR 1: Rising edge of THERMSHDN_END_RAW since last THERMSHDN_END_CLR
THERMWARN1_BGN_STATE	5	–	Unmaskable interrupt state, cleared by THERMWARN1_BGN_CLR.	0: No rising edge of THERMWARN1_BGN_RAW since last THERMWARN1_BGN_CLR 1: Rising edge of THERMWARN1_BGN_RAW since last THERMWARN1_BGN_CLR
THERMWARN1_END_STATE	4	–	Unmaskable interrupt state, cleared by THERMWARN1_END_CLR.	0: No rising edge of THERMWARN1_END_RAW since last THERMWARN1_END_CLR 1: Rising edge of THERMWARN1_END_RAW since last THERMWARN1_END_CLR
THERMFB_BGN_STATE	3	–	Unmaskable interrupt state, cleared by THERMFB_BGN_CLR.	0: No rising edge of THERMFB_BGN_RAW since last THERMFB_BGN_CLR 1: Rising edge of THERMFB_BGN_RAW since last THERMFB_BGN_CLR

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMFB_END_STATE	2	–	Unmaskable interrupt state, cleared by THERMFB_END_CLR.	0: No rising edge of THERMFB_END_RAW since last THERMFB_END_CLR 1: Rising edge of THERMFB_END_RAW since last THERMFB_END_CLR
OTP_FAIL_STATE	1	–	Unmaskable interrupt state, cleared by OTP_FAIL_CLR.	0: No rising edge of OTP_FAIL_RAW since last OTP_FAIL_CLR 1: Rising edge of OTP_FAIL_RAW since last OTP_FAIL_CLR
SPK_OVC_STATE	0	–	Unmaskable interrupt state, cleared by SPK_OVC_CLR.	0: No rising edge of SPK_OVC_RAW since last SPK_OVC_CLR 1: Rising edge of SPK_OVC_RAW since last SPK_OVC_CLR

Interrupt State 2 (0x2007)

BIT	7	6	5	4	3	2	1	0
Field	THERMWARN2_BGN_STATE	THERMWARN2_END_STATE	INT_SPKMON_ERR_STATE	INT_CLK_ERR_STATE	–	CLK_RECOVER_STATE	CLK_ERR_STATE	DMON_ERR_STATE

Access Type	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMSHDN_BGN_FLAG	7	–	Thermal shutdown begin event maskable interrupt flag. Masked by THERMSHDN_END_EN and cleared by THERMSHDN_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMSHDN_BGN_RAW since last THERMSHDN_BGN_CLR or THERMSHDN_BGN_EN is low 1: THERMSHDN_BGN_EN is high and rising edge of THERMSHDN_BGN_RAW since last THERMSHDN_BGN_CLR

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMSHDN_END_FLAG	6	–	Thermal shutdown end event maskable interrupt flag. Masked by THERMSHDN_END_EN and cleared by THERMSHDN_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMSHDN_END_RAW since last THERMSHDN_END_CLR or THERMSHDN_END_EN is low 1: THERMSHDN_END_EN is high and rising edge of THERMSHDN_END_RAW since last THERMSHDN_END_CLR
THERMWARN1_BGN_FLAG	5	–	Thermal-warning1 begin event maskable interrupt flag. Masked by THERMWARN1_BGN_EN and cleared by THERMWARN1_BGN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMWARN1_BGN_RAW since last THERMWARN1_BGN_CLR or THERMWARN1_BGN_EN is low 1: THERMWARN1_BGN_EN is high and rising edge of THERMWARN1_BGN_RAW since last THERMWARN1_BGN_CLR
THERMWARN1_END_FLAG	4	–	Thermal-warning1 end event maskable interrupt flag. Masked by THERMWARN1_END_EN and cleared by THERMWARN1_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMWARN1_END_RAW since last THERMWARN1_END_CLR or THERMWARN1_END_EN is low 1: THERMWARN1_END_EN is high and rising edge of THERMWARN1_END_RAW since last THERMWARN1_END_CLR
THERMFB_BGN_FLAG	3	–	Thermal foldback begin event maskable interrupt flag. Masked by THERMFB_BGN_EN and cleared by THERMFB_BGN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMFB_BGN_RAW since last THERMFB_BGN_CLR or THERMFB_BGN_EN is low 1: THERMFB_BGN_EN is high and rising edge of THERMFB_BGN_RAW since last THERMFB_BGN_CLR
THERMFB_END_FLAG	2	–	Thermal foldback end event maskable interrupt flag. Masked by THERMFB_END_EN and cleared by THERMFB_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMFB_END_RAW since last THERMFB_END_CLR or THERMFB_END_EN is low 1: THERMFB_END_EN is high and rising edge of THERMFB_END_RAW since last THERMFB_END_CLR
OTP_FAIL_FLAG	1	–	OTP load routine fail event maskable interrupt flag. Masked by OTP_FAIL_EN and cleared by OTP_FAIL_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of OTP_FAIL_RAW since last OTP_FAIL_CLR or OTP_FAIL_EN is low 1: OTP_FAIL_EN is high and rising edge of OTP_FAIL_RAW since last OTP_FAIL_CLR
SPK_OVC_FLAG	0	–	Speaker overcurrent event maskable interrupt flag. Masked by SPK_OVC_EN and cleared by SPK_OVC_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of SPK_OVC_RAW since last SPK_OVC_CLR or SPK_OVC_EN is low 1: SPK_OVC_EN is high and rising edge of SPK_OVC_RAW since last SPK_OVC_CLR

Interrupt Flag 2 (0x200C)

BIT	7	6	5	4	3	2	1	0
Field	THERMWARN2_BGN_FLAG	THERMWARN2_END_FLAG	INT_SPKMON_ERR_FLAG	INT_CLK_ERR_FLAG	–	CLK_RECOVER_FLAG	CLK_ERR_FLAG	DMON_ERR_FLAG
Reset	0b0	0b0	0b0	0x0	–	0x0	0x0	0b0
Access Type	Read Only	Read Only	Read Only	Read Only	–	Read Only	Read Only	Read Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
THERMWARN2_BGN_FLAG	7	–	Thermal-warning2 begin event maskable interrupt flag. Masked by THERMWARN2_BGN_EN and cleared by THERMWARN2_BGN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMWARN2_BGN_RAW since last THERMWARN2_BGN_CLR or THERMWARN2_BGN_EN is low 1: THERMWARN2_BGN_EN is high and rising edge of THERMWARN2_BGN_RAW since last THERMWARN2_BGN_CLR
THERMWARN2_END_FLAG	6	–	Thermal-warning2 end event maskable interrupt flag. Masked by THERMWARN2_END_EN and cleared by THERMWARN2_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of THERMWARN2_END_RAW since last THERMWARN2_END_CLR or THERMWARN2_END_EN is low 1: THERMWARN2_END_EN is high and rising edge of THERMWARN2_END_RAW since last THERMWARN2_END_CLR
INT_SPKMON_ERR_FLAG	5	–	Internal speaker data monitor error event maskable interrupt flag. Masked by INT_SPKMON_ERR_EN and cleared by INT_SPKMON_ERR_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of INT_SPKMON_ERR_RAW since last INT_SPKMON_ERR_CLR or INT_SPKMON_ERR_EN is low 1: INT_SPKMON_ERR_EN high and rising edge of INT_SPKMON_ERR_RAW since last INT_SPKMON_ERR_CLR
INT_CLK_ERR_FLAG	4	–	Internal clock monitor error event maskable interrupt flag. Masked by INT_CLK_ERR_EN and cleared by INT_CLK_ERR_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of INT_CLK_ERR_RAW since last INT_CLK_ERR_CLR or INT_CLK_ERR_EN is low 1: INT_CLK_ERR_EN high and rising edge of INT_CLK_ERR_RAW since last INT_CLK_ERR_CLR
CLK_RECOVER_FLAG	2	–	PCM input clock error recovery event maskable interrupt flag. Masked by CLK_RECOVER_EN and cleared by CLK_RECOVER_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of CLK_RECOVER_RAW since last CLK_RECOVER_CLR or CLK_RECOVER_EN is low 1: BCLK_RECOVER_EN high and rising edge of BCLK_RECOVER_RAW since last BCLK_RECOVER_CLR
CLK_ERR_FLAG	1	–	PCM input clock error event maskable interrupt flag. Masked by CLK_ERR_EN and cleared by CLK_ERR_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of CLK_ERR_RAW since last CLK_ERR_CLR or CLK_ERR_EN is low 1: CLK_ERR_EN high and rising edge of CLK_ERR_RAW since last CLK_ERR_CLR

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DMON_ERR_FLAG	0	–	PCM data input error event maskable interrupt flag. Masked by DMON_ERR_EN and cleared by DMON_ERR_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of DMON_ERR_RAW since last DMON_ERR_CLR or DMON_ERR_EN is low 1: DMON_ERR_EN high and rising edge of DMON_ERR_RAW since last DMON_ERR_CLR

BITFIELD	BITS	RES	DESCRIPTION	DECODE
PWRUP_DONE_FLAG	5	–	Device power-up done event maskable interrupt flag. Masked by PWRUP_DONE_EN and cleared by PWRUP_DONE_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of PWRUP_DONE_RAW since last PWRUP_DONE_CLR or PWRUP_DONE_EN is low 1: PWRUP_DONE_EN is high and rising edge of PWRUP_DONE_RAW since last PWRUP_DONE_CLR
PWRDN_DONE_FLAG	4	–	Device power-down done event maskable interrupt flag. Masked by PWRDN_DONE_EN and cleared by PWRDN_DONE_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of PWRDN_DONE_RAW since last PWRDN_DONE_CLR or PWRDN_DONE_EN is low 1: PWRDN_DONE_EN is high and rising edge of PWRDN_DONE_RAW since last PWRDN_DONE_CLR
PVDD_UVLO_SHDN_FLAG	3	–	PVDD supply UVLO event maskable interrupt flag. Masked by PVDD_UVLO_SHDN_EN and cleared by PVDD_UVLO_SHDN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of PVDD_UVLO_SHDN_RAW since last PVDD_UVLO_SHDN_CLR or PVDD_UVLO_SHDN_EN is low 1: PVDD_UVLO_SHDN_EN is high and rising edge of PVDD_UVLO_SHDN_RAW since last PVDD_UVLO_SHDN_CLR
VBAT_UVLO_SHDN_FLAG	2	–	VBAT supply UVLO event maskable interrupt flag. Masked by VBAT_UVLO_SHDN_EN and cleared by VBAT_UVLO_SHDN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of VBAT_UVLO_SHDN_RAW since last VBAT_UVLO_SHDN_CLR or VBAT_UVLO_SHDN_EN is low 1: VBAT_UVLO_SHDN_EN is high and rising edge of VBAT_UVLO_SHDN_RAW since last VBAT_UVLO_SHDN_CLR
DHT_ACTIVE_BGN_FLAG	1	–	DHT active begin event maskable interrupt flag. Masked by DHT_ACTIVE_BGN_EN and cleared by DHT_ACTIVE_BGN_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of DHT_ACTIVE_BGN_RAW since last DHT_ACTIVE_BGN_CLR or DHT_ACTIVE_BGN_EN is low 1: DHT_ACTIVE_BGN_EN is high and rising edge of DHT_ACTIVE_BGN_RAW since last DHT_ACTIVE_BGN_CLR

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DHT_ACTIVE_END_FLAG	0	–	DHT active end event maskable interrupt flag. Masked by DHT_ACTIVE_END_EN and cleared by DHT_ACTIVE_END_CLR. If IRQ is enabled, an interrupt is generated on a flag bit rising edge.	0: No rising edge of DHT_ACTIVE_END_RAW since last DHT_ACTIVE_END_CLR or DHT_ACTIVE_END_EN is low 1: DHT_ACTIVE_END_EN is high and rising edge of DHT_ACTIVE_END_RAW since last DHT_ACTIVE_END_CLR

Interrupt Flag 4 (0x200E)

Access Type	Write, Read				Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
UNMUTE_THRESH	7:4	NG	Sets the threshold (number of LSBs toggling) at which the noise gate/idle mode deactivates.	0x0: 1 LSB 0x1: 2 LSBs 0x2: 3 LSBs 0x3: 4 LSBs 0x4: 5 LSBs 0x5: 6 LSBs 0x6: 7 LSBs 0x7: 8 LSBs 0x8: 9 LSBs 0x9: 10 LSBs 0xA to 0xF: Reserved
MUTE_THRESH	3:0	NG	Sets the threshold (number of LSBs toggling) at which the noise gate/Idle mode is activated.	0x0: 1 LSB 0x1: 2 LSBs 0x2: 3 LSBs 0x3: 4 LSBs 0x4: 5 LSBs 0x5: 6 LSBs 0x6: 7 LSBs 0x7: 8 LSBs 0x8: 9 LSBs 0x9: 10 LSBs 0xA to 0xF: Reserved

Noise Gate/Idle Mode Enables (0x2033)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	NOISEGATE_EN
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
NOISEGATE_EN	0	–	Enables the noise gate.	0: Noise gate disabled 1: Noise gate enabled

Clock Monitor Control (0x2038)

BIT	7	6	5	4	3	2	1	0
Field	–	CMON_BSELTOL[2:0]			CMON_ERRTOL[2:0]			CMON_AUTORESTART_EN
Reset	–	0b0			0x0			0x0
Access Type	–	Write, Read			Write, Read			Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
CMON_BSELTOL	6:4	EN	The number of frames of incorrect or correct clock ratio (BCLKs per LRCLK) needed to trigger or recover from a framing error.	0x0: Trigger after 1 incorrect LRCLK frame, recover after 1 correct LRCLK frame 0x1: Trigger after 2 incorrect LRCLK frames, recover after 16 correct LRCLK frames 0x2: Trigger after 3 incorrect LRCLK frames, recover after 24 correct LRCLK frame 0x3: Trigger after 4 incorrect LRCLK frames, recover after 32 correct LRCLK frames 0x4: Trigger after 5 incorrect LRCLK frames, recover after 40 correct LRCLK frames 0x5: Trigger after 6 incorrect LRCLK frames, recover after 48 correct LRCLK frames 0x6: Trigger after 7 incorrect LRCLK frames, recover after 56 correct LRCLK frames 0x7: Trigger after 8 incorrect LRCLK frames, recover after 64 correct LRCLK frames

BITFIELD	BITS	RES	DESCRIPTION	DECODE
CMON_ERRTOL	3:1	EN	Selects the number of incorrect or correct LRCLK periods needed to trigger or recover from a frame clock rate error.	0x0: Trigger after 1 incorrect LRCLK frame, recover after 1 correct LRCLK frame 0x1: Trigger after 2 incorrect LRCLK frames, recover after 16 correct LRCLK frames 0x2: Trigger after 3 incorrect LRCLK frames, recover after 24 correct LRCLK frames 0x3: Trigger after 4 incorrect LRCLK frames, recover after 32 correct LRCLK frames 0x4: Trigger after 5 incorrect LRCLK frames, recover after 40 correct LRCLK frames 0x5: Trigger after 6 incorrect LRCLK frames, recover after 48 correct LRCLK frames 0x6: Trigger after 7 incorrect LRCLK frames, recover after 56 correct LRCLK frames 0x7: Trigger after 8 incorrect LRCLK frames, recover after 64 correct LRCLK frames
CMON_AUTORESTART_EN	0	EN	Controls whether or not the device automatically resumes playback when the clocks become valid after the device is disabled due to a clock monitor error.	0: Device does not automatically restart after valid clocks are reapplied. 1: Device automatically restarts after valid clocks are reapplied.

Data Monitor Control (0x2039)

BIT	7	6	5	4	3	2	1	0
Field	–	–	DMON_MAG_THRES[1:0]		DMON_STUCK_THRES[1:0]		DMON_DURATION[1:0]	
Reset	–	–	0x0		0x0		0x0	
Access Type	–	–	Write, Read		Write, Read		Write, Read	

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DMON_MAG_THRES	5:4	EN	Sets the data magnitude error threshold that the input PCM amplitude level is compared against. If the input signal is above this threshold for longer than the DMON_DURATION, data monitor error is asserted.	0x0: -30.1030dB (5-bits) 0x1: -24.0824dB (4-bits) 0x2: -18.0618dB (3-bits) 0x3: -12.0412dB (2-bits)
DMON_STUCK_THRES	3:2	EN	Sets the data stuck error threshold that the input PCM amplitude level is compared against. If the input signal is stuck at the same value above this threshold for longer than the DMON_DURATION, data monitor error is asserted.	0x0: 15-bits (-90.3090dBFS) 0x1: 13-bits (-78.2678dBFS) 0x2: 11-bits (-66.2266dBFS) 0x3: 9-bits (-54.1854dBFS)

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DMON_DURATION	1:0	EN	Sets the time duration over which the Data Monitor must consecutively detect erroneous input PCM data before asserting a data monitor error.	0x0: 64ms 0x1: 256ms 0x2: 1024ms 0x3: 4096ms

Speaker Monitor Threshold (0x203A)

BIT	7	6	5	4	3	2	1	0
Field	SPKMON_THRESH[7:0]							
Reset	0d58							
Access Type	Write, Read							

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPKMON_THRESH	7:0	–	Sets the speaker power threshold. If the signal power recovered by the circuit is above this threshold for longer than the DMON_DURATION, speaker monitor error is asserted. Threshold is calculated as % of f_S. Full-scale means the output voltage hit the rails. The voltage threshold can be calculated from the register setting using the following equation: **Threshold (voltage) = (SPKMON_THRESH/160) x Active Class-D Supply Voltage**	Threshold = (SPKMON_THRESH*2)/320

Speaker Monitor Duration (0x203B)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	SPKMON_DURATION[3:0]			
Reset	–	–	–	–	0x2			
Access Type	–	–	–	–	Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPKMON_ DURATION	3:0	–	Sets the time duration over which the speaker monitor must consecutively detect power above threshold before asserting a speaker monitor error.	**Value**: **Decode** 0x0: 10ms 0x1: 25ms 0x2: 50ms 0x3: 75ms 0x4: 100ms 0x5: 200ms 0x6: 300ms 0x7: 400ms 0x8: 500ms 0x9: 600ms 0xA: 700ms 0xB: 800ms 0xC: 900ms 0xD: 1000ms 0xE: 1100ms 0xF: 1200ms

Enable Controls (0x203F)

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPKMON_ EN	3	ENL	Enables the internal speaker protection monitor	0x0: Disable internal speaker data monitor 0x1: Enable internal speaker data monitor
DMON_MA G_EN	2	ENL	Enables the data monitor circuit to monitor PCM input data for large magnitude (DC) audio	0: Data magnitude check disabled 1: Data magnitude check enabled
DMON_ST UCK_EN	1	ENL	Enables the data monitor circuit to monitor PCM input for stuck data.	0: Data Stuck-AT monitor disabled 1: Data Stuck-AT monitor enabled
CMON_EN	0	ENL	Enables the clock monitor to monitor PCM input clocks for clock errors.	0: Clock monitor disabled 1: Clock monitor enabled

Pin Config (0x2040)

BIT	7	6	5	4	3	2	1	0
Field	LV_EN_DRV[1:0]		ICC_DRV[1:0]		IRQ_DRV[1:0]		DOUT_DRV[1:0]	
Reset	0x1		0x1		0x1		0x1	
Access Type	Write, Read		Write, Read		Write, Read		Write, Read	

BITFIELD	BITS	RES	DESCRIPTION	DECODE
LV_EN_DR V	7:6	–	Configures the output drive strength of LV_EN pin.	0x0: Reduced drive mode 0x1: Normal drive mode 0x2: High drive mode 0x3: Maximum drive mode

BITFIELD	BITS	RES	DESCRIPTION	DECODE
ICC_DRV	5:4	ICC	Configures the output drive strength of ICC pin.	00: Reduced drive mode 01: Normal drive mode 10: High drive mode 11: Maximum drive mode
IRQ_DRV	3:2	IRQ	Configures the output drive strength of IRQ pin.	00: Reduced drive mode 01: Normal drive mode 10: High drive mode 11: Maximum drive mode
DOUT_DRV	1:0	TXEN	Configures the output drive strength of DOUT pin.	00: Reduced drive mode 01: Normal drive mode 10: High drive mode 11: Maximum drive mode

PCM Mode Config (0x2041)

BIT	7	6	5	4	3	2	1	0
Field	PCM_CHANSZ[1:0]		PCM_FORMAT[2:0]			PCM_TX_INTERLEAVE	PCM_CHANSEL	PCM_TX_EXTRA_HIZ
Reset	0x3		0x0			0x0	0b0	0b0
Access Type	Write, Read		Write, Read			Write, Read	Write, Read	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
PCM_CHANSZ	7:6	ENL	Configures the PCM data word size for each channel.	00: Reserved 01: 16-bit 10: 24-bit 11: 32-bit
PCM_FORMAT	5:3	ENL	Selects the PCM data format.	0x0: I^2S mode 0x1: Left-justified 0x2: Reserved 0x3: TDM mode 0 (0 BCLK delay from LRCLK) 0x4: TDM mode 1 (1 BCLK delay from LRCLK) 0x5: TDM mode 2 (2 BCLK delay from LRCLK) 0x6 to 0x7: Reserved
PCM_TX_INTERLEAVE	2	ENL	Controls whether or not I/V sense data assigned to the same channel is frame interleaved on the PCM data output (DOUT).	0: Disable interleave mode 1: Enable interleave mode
PCM_CHANSEL	1	ENL	Selects which LRCK edge starts a new frame (Channel 0 or Slot 0).	0: I^2S and left-justified mode: Falling LRCLK edge starts a new frame. In TDM modes: Rising LRCLK edge starts a new frame. 1: In I^2S and left-justified mode: Rising LRCLK edge starts a new frame. In TDM modes: Falling LRCLK edge starts a new frame.

BITFIELD	BITS	RES	DESCRIPTION	DECODE
PCM_TX_EXTRA_HIZ	0	ENL	Select whether DOUT is driven to zero or Hi-Z during extra BCLK cycles in I^2S and left-justified mode.	0: Drive DOUT to zero for extra BCLK cycles 1: Drive DOUT to Hi-Z for extra BCLK cycles

PCM Clock Setup (0x2042)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	PCM_BCLKEDGE	PCM_BSEL[3:0]			
Reset	–	–	–	0b0	0x4			
Access Type	–	–	–	Write, Read	Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
PCM_BCLKEDGE	4	ENL	Selects the active BCLK edge.	0: Input data captured and output data valid on rising edge of BCLK 1: Input data captured and output data valid on falling edge of BCLK
PCM_BSEL	3:0	ENL	Selects the number of BCLKs per LRCLK expected by the PCM Interface.	0x0: Reserved 0x1: Reserved 0x2: 32 0x3: 48 0x4: 64 0x5: 96 0x6: 128 0x7: 192 0x8: 256 0x9: 384 0xA: 512 0xB: 320 0xC: 250 0xD: 125 0xE to 0xF: Reserved

PCM Sample Rate Setup 1 (0x2043)

BIT	7	6	5	4	3	2	1	0
Field	IVADC_SR[3:0]				PCM_SR[3:0]			
Reset	0x8				0x8			
Access Type	Write, Read				Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
IVADC_SR	7:4	ENL	Sets the sample rate of the I/V sense ADC path.	0x0: 8kHz 0x1: 11.025kHz 0x2: 12kHz 0x3: 16kHz 0x4: 22.05kHz 0x5: 24kHz 0x6: 32kHz 0x7: 44.1kHz 0x8: 48kHz 0x9: 88.2kHz 0xA: 96kHz 0xB: 176.4kHz 0xC: 192kHz 0xD to 0xF: Reserved
PCM_SR	3:0	ENL	Sets the sample rate of the PCM interface. This corresponds to the expected LRCLK frequency.	0x0: 8kHz 0x1: 11.025kHz 0x2: 12kHz 0x3: 16kHz 0x4: 22.05kHz 0x5: 24kHz 0x6: 32kHz 0x7: 44.1kHz 0x8: 48kHz 0x9: 88.2kHz 0xA: 96kHz 0xB: 176.4kHz 0xC: 192kHz 0xD to 0xF: Reserved

BIT	7	6	5	4	3	2	1	0
Field	–	–	SPK_DG_DELAY[5:0]					
Reset	–	–	0x0					
Access Type	–	–	Write, Read					

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_DG_DELAY	5:0	SPK	Selects the speaker amplifier path signal delay for DG mode operation. Delays the audio output by N samples (N x f_S).	0x0: No delay 0x1: Delay 1 sample 0x2: Delay 2 samples 0x3 to 0x1D: ... (1 sample step) 0x1E: Delay 30 samples 0x1F: Delay 31 samples 0x20: Delay 32 samples

SPK Class DG Mode (0x2098)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	SPK_MODE[1:0]	
Reset	–	–	–	–	–	–	0x0	
Access Type	–	–	–	–	–	–	Write, Read	

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_MODE	1:0	–	Selects the speaker amplifier operating mode.	0x0: DG mode is enabled. 0x1: DG mode is disabled and amplifier is always supplied from PVDD pin. 0x2: DG mode is disabled and amplifier is supplied from VBAT pin when supply conditions are met. 0x3: Reserved

SPK Class DG VBAT Level (0x2099)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	VBATLOW_OK_LVL[2:0]		
Reset	–	–	–	–	–	0x3		
Access Type	–	–	–	–	–	Write, Read		

BITFIELD	BITS	RES	DESCRIPTION	DECODE
VBATLOW_OK_LVL	2:0	–	Sets the threshold for VBAT level below which the amplifier is forced to operate in PVDD mode only (i.e., the active amplifier supply is PVDD only).	0x0: 2.5V 0x1: 2.6V 0x2: 2.7V 0x3: 2.8V 0x4: 2.9V 0x5: 3.0V 0x6: Reserved 0x7: Reserved

SPK Edge Control (0x209A)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	SPK_FSW_SEL	–	–
Reset	–	–	–	–	–	0x0	–	–
Access Type	–	–	–	–	–	Write, Read	–	–

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_FSW_SEL	2	SPK	Controls the nominal switching frequency of the speaker amplifier.	0: 472kHz 1: 666kHz

SPK Path Wideband Only Enable (0x209B)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	SPK_WIDEBAND_ONLY_EN
Reset	–	–	–	–	–	–	–	0b00
Access Type	–	–	–	–	–	–	–	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_WIDEBAND_ONLY_EN	0	SPK	When enabled, only wideband signal is sent to the Amplifier	0x0: Ultrasound Signal Mode Disable 0x1: Ultrasound Signal Mode Enable

SPK Edge Control 1 (0x209C)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	SPK_SL_RATE_GMODE[3:0]			
Reset	–	–	–	–	0xA			
Access Type	–	–	–	–	Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_SL_RATE_GMODE	3:0	–	These bits control the on/off time of high side power FET connected to the VBAT supply pin. This in effect strongly controls rise time at OUTx nodes in VBAT mode, and weakly controls fall time at OUTx nodes in VBAT mode, as fall time is strongly controlled by SPK_SL_RATE_LS<3:0>.	Previous four codes are preferred choices.

SPK Edge Control 2 (0x209D)

BIT	7	6	5	4	3	2	1	0
Field	SPK_SL_RATE_LS[3:0]				SPK_SL_RATE_HS[3:0]			
Reset	0xA				0xA			
Access Type	Write, Read				Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_SL_RATE_LS	7:4	–	These bits control the on/off time of the low side power FET. This in effect strongly controls fall time at OUTx node, and weakly controls rise time at OUTx nodes. Rise times are strongly controlled by SPK_SL_RATE_GMODE in VBAT mode and SPK_SL_RATE_HS in PVDD mode.	Previous table shows four preferred codes.
SPK_SL_RATE_HS	3:0	–	These bits control the on/off time of high side power FET connected to the PVDD supply pin. This in effect strongly controls rise time at OUTx nodes, and weakly controls fall time of OUTx nodes in PVDD mode. Fall time is strongly controlled by SPK_SL_RATE_LS.	Previous table shows the preferred four codes.

Amp Clip Gain (0x209E)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	SPK_GAIN[3:0]			
Reset	–	–	–	–	0x0			
Access Type	–	–	–	–	Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
SPK_GAIN	3:0	–	Sets the digital clip gain level of the speaker amplifier path.	0x00: 0dB 0x01: 0.5dB 0x02: 1.0dB 0x03: 1.5dB 0x04: 2.0dB 0x05: 2.5dB 0x06: 3.0dB 0x07: 3.5dB 0x08: 4.0dB 0x09: 5.0dB 0x0A: 6.0dB 0x0B to 0x0F: Reserved

BITFIELD	BITS	RES	DESCRIPTION	DECODE
MEAS_ADC_THERM_RD_UPD	2	–	Write 1 to inititate a measurement and lock the result into the measurement ADC thermal channel readback register	0: No effect 1: Inititates a measurement and locks the result into the measurement ADC channel readback register
MEAS_ADC_VBAT_RD_UPD	1	–	Write 1 to inititate a measurement and locks the result into the measurement ADC VBAT channel readback register	0: No effect 1: Inititates a measurement and locks the result into the measurement ADC channel readback register
MEAS_ADC_PVDD_RD_UPD	0	–	Write 1 to inititate a measurement and lock the result into the measurement ADC PVDD channel readback register	0: No effect 1: Inititates a measurement and locks the result into the measurement ADC channel readback register

Meas ADC PVDD Readback MSB (0x20B6)

BIT	7	6	5	4	3	2	1	0
Field	MEAS_ADC_PVDD_DATA[8:1]							
Reset	0x0							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_PVDD_DATA	7:0	–	Provides the measured PVDD value. To convert the 9-bit code into a real voltage, use the following: Measured V_{PVDD} (V) = 2.5V + MEAS_ADC_PVDD_DATA[8:0] x 0.038085V

Meas ADC PVDD Readback LSB (0x20B7)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	MEAS_ADC_PVDD_DATA[0]
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Read Only

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_PVDD_DATA	0	–	Provides the measured PVDD value. To convert the 9-bit code into a real voltage, use the following: Measured V_{PVDD} (V) = 2.5V + MEAS_ADC_PVDD_DATA[8:0] x 0.038085V

Meas ADC VBAT Readback MSB (0x20B8)

BIT	7	6	5	4	3	2	1	0
Field	MEAS_ADC_VBAT_DATA[8:1]							
Reset	0x0							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_VBAT_DATA	7:0	–	Provides the measured VBAT value. To convert the 9-bit code into a real voltage, use the following: Measured V_{VBAT} (V) = 1.25V + MEAS_ADC_VBAT_DATA[8:0] x 0.01904V

Meas ADC VBAT Readback LSB (0x20B9)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	MEAS_ADC_VBAT_DATA[0]
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Read Only

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_VBAT_DATA	0	–	Provides the measured VBAT value. To convert the 9-bit code into a real voltage, use the following: Measured V_{VBAT} (V) = 1.25V + MEAS_ADC_VBAT_DATA[8:0] x 0.01904V

Meas ADC Temp Readback MSB (0x20BA)

BIT	7	6	5	4	3	2	1	0
Field	MEAS_ADC_THERM_DATA[8:1]							
Reset	0x0							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_THERM_DATA	7:0	–	Provides the measured temperature value. To convert the 9-bit code into a real temperature, use the following: Measured Temperature (°C) = (MEAS_ADC_THERM_DATA[8:0] x 1.0°C) - 208°C

Meas ADC Temp Readback LSB (0x20BB)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	MEAS_ADC_THERM_DATA[0]
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Read Only

BITFIELD	BITS	RES	DESCRIPTION
MEAS_ADC_THERM_DATA	0	–	Provides the measured temperature value. To convert the 9-bit code into a real temperature, use the following: Measured Temperature (°C) = (MEAS_ADC_THERM_DATA[8:0] x 1.0°C) - 208°C

Meas ADC Lowest PVDD Readback MSB (0x20BC)

BIT	7	6	5	4	3	2	1	0
Field	LOWEST_PVDD_DATA[8:1]							
Reset	0xFF							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION
LOWEST_PVDD_DATA	7:0	–	Provides the lowest measured PVDD value. To convert the 9-bit code into a real voltage, use the following: Measured V_{PVDD} (V) = 2.5V + MEAS_ADC_PVDD_DATA[8:0] x 0.038085V

Meas ADC Lowest PVDD Readback LSB (0x20BD)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	LOWEST_PVDD_DATA[0]
Reset	–	–	–	–	–	–	–	0x1
Access Type	–	–	–	–	–	–	–	Read, Ext

BITFIELD	BITS	RES	DESCRIPTION
LOWEST_PVDD_DATA	0	–	Provides the lowest measured PVDD value. To convert the 9-bit code into a real voltage, use the following: Measured V_{PVDD} (V) = 2.5V + MEAS_ADC_PVDD_DATA[8:0] x 0.038085V

Meas ADC Lowest VBAT Readback MSB (0x20BE)

BIT	7	6	5	4	3	2	1	0
Field	LOWEST_VBAT_DATA[8:1]							
Reset	0xFF							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION
LOWEST_VBAT_DATA	7:0	–	Provides the measured VBAT value. To convert the 9-bit code into a real voltage, use the following: Measured V_{VBAT} (V) = 1.25V + MEAS_ADC_VBAT_DATA[8:0] x 0.01904V

Meas ADC Lowest VBAT Readback LSB (0x20BF)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	LOWEST_VBAT_DATA[0]
Reset	–	–	–	–	–	–	–	0x1
Access Type	–	–	–	–	–	–	–	Read, Ext

BITFIELD	BITS	RES	DESCRIPTION
LOWEST_VBAT_DATA	0	–	Provides the measured VBAT value. To convert the 9-bit code into a real voltage, use the following: Measured V_{VBAT} (V) = 1.25V + MEAS_ADC_VBAT_DATA[8:0] x 0.01904V

Meas ADC Config (0x20C7)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	MEAS_ADC_VBAT_EN	MEAS_ADC_PVDD_EN
Reset	–	–	–	–	–	–	0x0	0x0
Access Type	–	–	–	–	–	–	Write, Read	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
MEAS_ADC_VBAT_EN	1	–	Manually enables the measurement ADC VBAT channel.	0: Do not manually enable the measurement ADC channel (may be automatically enabled) 1: Manually force the measurement ADC channel to be enabled anytime the device is in the active state
MEAS_ADC_PVDD_EN	0	–	Manually enables the measurement ADC PVDD channel.	0: Do not manually enable the measurement ADC channel (may be automatically enabled) 1: Manually force the measurement ADC channel to be enabled anytime the device is in the active state

DHT Configuration 1 (0x20D0)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	DHT_VROT_PNT[3:0]			
Reset	–	–	–	–	0x0			
Access Type	–	–	–	–	Write, Read			

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DHT_VROT_PNT	3:0	DHT	Sets the DRC rotation point.	0x0: 0dBFS 0x1: -1dBFS 0x2: -2dBFS 0x3: -3dBFS 0x4: -4dBFS 0x5: -5dBFS 0x6: -6dBFS 0x7: -8dBFS 0x8: -10dBFS 0x9: -12dBFS 0xA: -15dBFS 0xB: Reserved 0xC: Reserved 0xD: Reserved 0xE: Reserved 0xF: Reserved

Limiter Configuration 1 (0x20D1)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	DHT_HR[4:0]				
Reset	–	–	–	0x8				
Access Type	–	–	–	Write, Read				

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DHT_HR	4:0	–	Selects the DHT supply headroom for the DRC and limiter functions.	0x0: -20% 0x1: -17.5% 0x2: -15% 0x3: -12.5% 0x4: -10% 0x5: -7.5% 0x6: -5.0% 0x7: -2.5% 0x8: 0% 0x9: +2.5% 0xA: +5.0% 0xB: +7.5% 0xC: +10% 0xD: +12.5% 0xE: +15% 0xF: +17.5% 010: +20%

Limiter Configuration 2 (0x20D2)

BIT	7	6	5	4	3	2	1	0
Field	–	–	DHT_LIM_THRESH[4:0]					DHT_LIM_MODE
Reset	–	–	0x0					0x0
Access Type	–	–	Write, Read					Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DHT_LIM_THRESH	5:1	DHT	Selects the fixed threshold level for signal level limiter mode (SLL). Has no effect in signal distortion limiter mode (SDL).	00000: 0dBFS 00001: -1dBFS 00010: -2dBFS ...: (-1dBFS steps) 01110: -14dBFS 01111: -15dBFS 10000 to 11111: Reserved
DHT_LIM_MODE	0	DHT	Selects whether the DHT limiter is in signal distortion or signal level limiter mode.	0: Signal distortion limiter mode where limiter threshold tracks supply 1: Signal level limiter mode where limiter uses fixed thresholds

DHT Configuration 2 (0x20D3)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	DHT_MAX_ATN[4:0]				
Reset	–	–	–	0x14				
Access Type	–	–	–	Write, Read				

BITFIELD	BITS	RES	DESCRIPTION	DECODE
DHT_MAX_ATN	4:0	DHT	Selects the maximum attenuation that can be applied to the audio signal by the DHT.	0x0: Reserved 0x1: -1dB 0x2: -2dB 0x3: -3dB 0x4: -4dB 0x5: -5dB 0x6: -6dB 0x7: -7dB 0x8: -8dB 0x9: -9dB 0xA: -10dB 0xB: -11dB 0xC: -12dB 0xD: -13dB 0xE: -14dB 0xF: -15dB 0x10: -16dB 0x11: -17dB 0x12: -18dB 0x13: -19dB 0x14: -20dB 0x15-0x1F: Reserved

BPE Threshold Hysteresis (0x2106)

BIT	7	6	5	4	3	2	1	0
Field	BPE_VTHRESH_HYST[7:0]							
Reset	0x0							
Access Type	Write, Read							

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_VTHRESH_HYST	7:0	BPE	Sets the hysteresis to move up to the next level in the brownout controller. Refer to the Measurement ADC PVDD or VBAT channel result register to set these levels.	00000000: No hysteresis 00000001: 1 LSB of hysteresis 00000010: 2 LSBs of hysteresis ...: 1 LSB steps 11111101: 253 LSBs of hysteresis 11111110: 254 LSBs of hysteresis 11111111: 255 LSBs of hysteresis

BPE Infinite Hold Clear (0x2107)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	BPE_HLD_RLS
Reset	–	–	–	–	–	–	–	
Access Type	–	–	–	–	–	–	–	Write Only

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_HLD_RLS	0	BPE	Manually releases the BPE controller when infinite hold is enabled.	0x0: Writing 0 has no effect 0x1: Release brownout-prevention-engine controller from infinite hold

BPE Supply Source (0x2108)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	BPE_SRC_SEL
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_SRC_SEL	0	BPE	This bit selects the measurement ADC channel that is used as the input to the brownout-prevention-engine controller.	0x0: Measurement ADC PVDD channel is the input to the BPE controller 0x1: Measurement ADC VBAT channel is the input to the BPE controller

BPE Lowest State (0x2109)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	BPE_LOWEST[2:0]		
Reset	–	–	–	–	–	0x0		
Access Type	–	–	–	–	–	Read, Ext		

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_LOWEST	2:0	–	Returns the lowest level the brownout-prevention engine has transitioned to. Upon reading the register it is updated to show the current level of the brownout controller.	000: Brownout inactive—normal operation 001: Level 3 010: Level 2 011: Level 1 100: Level 0 101 to 111: Reserved

BPE Lowest Gain (0x210A)

BIT	7	6	5	4	3	2	1	0
Field	BPE_LOWEST_GAIN[7:0]							
Reset	0x0							
Access Type	Read, Ext							

BITFIELD	BITS	RES	DESCRIPTION
BPE_LOWEST_GAIN	7:0	–	Returns the lowest gain (highest gain attenuation) applied by the brownout-prevention engine since the register was last read. Gain format: 5 bit integer and 3 bit fraction. Integer part is 1dB per step while fractional part is 1/8dB per step.

BPE Lowest Limiter (0x210B)

BIT	7	6	5	4	3	2	1	0
Field	BPE_LOWEST_LIMIT[7:0]							
Reset	0x0							
Access Type	Read, Ext							

BITFIELD	BITS	RES	DESCRIPTION
BPE_LOWEST_LIMIT	7:0	–	Returns the lowest limiter setting applied by the brownout-prevention engine since the register was last read. Limiter format: 4 bit integer and 4 bit fraction. Integer part is 1dB per step while fractional part is 1/16dB per step.

BPE Enable (0x210D)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	BPE_LIM_EN	BPE_EN
Reset	–	–	–	–	–	–	0x0	0x0
Access Type	–	–	–	–	–	–	Write, Read	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
BPE_LIM_EN	1	EN	Enables BPE Limiter function	0x0: BPE Limiter disabled 0x1: BPE Limiter enabled
BPE_EN	0	–	Enables BPE function	0x0: BPE disabled 0x1: BPE enabled

Auto-Restart Behavior (0x210E)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	OVC_AUTORESTART_EN	THERM_AUTORESTART_EN	VBAT_AUTORESTART_EN	PVDD_AUTORESTART_EN
Reset	–	–	–	–	0b0	0b0	0b0	0b0
Access Type	–	–	–	–	Write, Read	Write, Read	Write, Read	Write, Read

BITFIELD	BITS	RES	DESCRIPTION	DECODE
OVC_AUTORESTART_EN	3	EN	Controls whether or not the speaker amplifier is automatically reenabled after an overcurrent fault condition.	0: Overcurrent recovery is in manual mode 1: Overcurrent recovery is in auto mode
THERM_AUTORESTART_EN	2	EN	Controls whether or not the device automatically returns to the active state when the die temperature recovers from thermal shutdown.	0: Thermal shutdown recovery is in manual mode 1: Thermal shutdown recovery is in auto mode

BITFIELD	BITS	RES	DESCRIPTION	DECODE
VBAT_AUTORESTART_EN	1	EN	Controls whether or not the device automatically returns to the active state when VBAT recovers from UVLO event.	0: VBAT UVLO recovery is in manual mode 1: VBAT UVLO recovery is in auto mode
PVDD_AUTORESTART_EN	0	EN	Controls whether or not the device automatically returns to the active state when PVDD recovers from UVLO event.	0: PVDD UVLO recovery is in manual mode 1: PVDD UVLO recovery is in auto mode

Global Enable (0x210F)

BIT	7	6	5	4	3	2	1	0
Field	–	–	–	–	–	–	–	EN
Reset	–	–	–	–	–	–	–	0x0
Access Type	–	–	–	–	–	–	–	Write, Read, Ext

BITFIELD	BITS	RES	DESCRIPTION	DECODE
EN	0	–	Disable or enable all blocks and reset all logic except the I^2C interface and control registers.	0: Device powered down 1: Device enabled

Revision ID (0x21FF)

BIT	7	6	5	4	3	2	1	0
Field	REV_ID[7:0]							
Reset	0x40							
Access Type	Read Only							

BITFIELD	BITS	RES	DESCRIPTION	DECODE
REV_ID	7:0	–	Revision of the device. Updated at every device revision.	0x40: Device revision

Applications Information

Layout and Grounding

Proper layout and grounding are essential for optimal performance; use at least four PCB layers and add thermal vias to the ground/power plane close to the device to ensure good thermal performance and high-end output power. Good grounding improves audio performance and prevents switching noise from coupling into the audio signal. Ground the power signals and the analog signals of the IC separately at the system ground plane to prevent switching interference from corrupting sensitive analog signals. Place the recommended supply decoupling capacitors as close as possible to the IC. The PVDD to PGND connection must be kept short and should have minimal trace length and loop area to ensure optimal performance. Use wide, low-resistance output, supply, and ground traces. As load impedance decreases, the current drawn from the device outputs increase. At higher current, the resistance of the output traces decreases the power delivered to the load. For example, if 2W is delivered from the speaker output to a 4Ω load through a 100mΩ trace, 49mW is consumed in the trace. If power is delivered through a 10mΩ trace, only 5mW is consumed in the trace. Wide output, supply, and ground traces also improve the power dissipation of the device. The device is inherently designed for excellent RF immunity. For best performance, add ground fills around all signal traces on the top and bottom PCB planes. It is advisable to follow the layout of the MAX98396 EV kit as closely as possible in the application. Thermal and performance measurements shown in this data sheet were measured with a 6-layer board (θ_{JA} = 33°C/W). As a result, the EV kit performance is likely better than what can be achieved with a JEDEC standard board.

Recommended External Components

Table 12 shows the recommended external components. See the *Typical Application Circuits* for more details.

Table 12. Component List

BUMP	VALUE	SIZE	VOLTAGE RATING (V)	DIELECTRIC
PVDD	220µF ± 20%	—	35	Alum-Elec
PVDD	10µF ± 20%	0603	25	X5R
PVDD	10µF ± 20%	0603	25	X5R
PVDD	0.1µF ± 10%	0402	25	X5R
PVDD	0.1µF ± 10%	0402	25	X5R
VBAT	1µF	0201	16	X5R
VBAT	10µF	0603	25	X5R
VREFC	1µF ± 20%	0201	6.3	X5R
DVDD	1µF ± 20%	0201	6.3	X5R
DVDDIO	1µF ± 20%	0201	6.3	X5R
AVDD	1µF ± 20%	0201	6.3	X5R

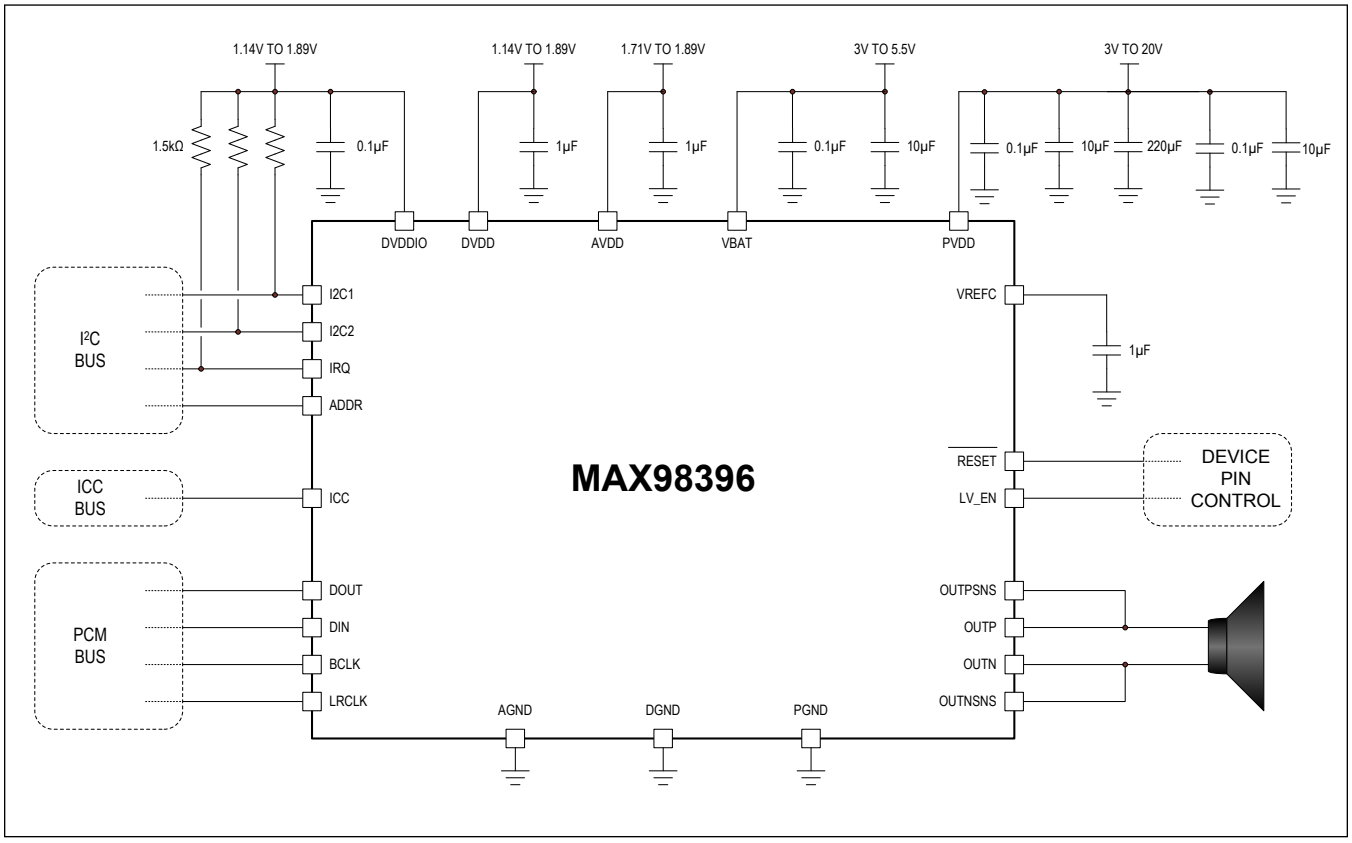
Typical Application Circuit



Ordering Information

PART NUMBER	TEMP RANGE	PIN-PACKAGE
MAX98396EWB+	-40°C to +85°C	35 WLP
MAX98396EWB+T	-40°C to +85°C	35 WLP

+Denotes a lead(Pb)-free/RoHA-compliant package.

T = Tape and reel.

Revision History

REVISION NUMBER	REVISION DATE	DESCRIPTION	PAGES CHANGED
0	3/21	Initial release	—
1	4/21	Added *Package Information* section, updated *Electrical Characteristics* table, updated supported TDM mode configurations in Table 5, added SPK_WIDEBAND_ONLY_EN bit to register map	10, 11-14, 16, 22, 24, 43, 44, 91, 138
