

POWER FACTOR CORRECTION CONTROLLER**AP1661****General Description**

The AP1661 is an active power factor control IC which is designed mainly for use as pre-converter in electronic ballast, AC-DC adapters and off-line SMPS applications.

The AP1661 includes an internal start-up timer for stand-alone applications, a one-quadrant multiplier to realize near unity power factor and a zero current detector to ensure DCM boundary conduction operation. The totem pole output stage is capable of driving power MOSFET with 600mA source current and 800mA sink current.

Designed with advanced BiCMOS process, the AP1661 features low start-up current, low operation current and low power dissipation. The AP1661 also has rich protection features including over-voltage protection, input under-voltage lockout with hysteresis and multiplier output clamp to limit maximum peak current.

This IC is available in SOIC-8 and DIP-8 packages.

Features

- Zero Current Detection Control for DCM Boundary Conduction Mode
- Adjustable Output Voltage with Precise Over-Voltage Protection
- Low Start-up Current with 50 μ A Typical Value
- Low Operating Supply Current with 4mA Typical Value
- 1% Precision Internal Reference Voltage
- Internal Start-up Timer
- Disable Function for Reduced Current Consumption
- Totem Pole Output with 600mA Source Current and 800mA Sink Current Capability
- Under-Voltage Lockout with 2.5V of Hysteresis

Applications

- AC-DC Adapter
- Off-line SMPS
- Electronic Ballast

POWER FACTOR CORRECTION CONTROLLER

AP1661

Functional Block Description

AP1661 is a high performance power factor correction controller which operates in DCM boundary conduction mode. The PFC converter's switch will be turned on when the inductor current reduces to zero and turned off when the sensed inductor current reaches the required reference which is decided by the output of multiplier.

Error Amplifier and Over-Voltage Protection

The error amplifier regulates the PFC output voltage. The internal reference on the non-inverting input of the error amplifier is 2.5V. The error amplifier's inverting input (INV) is connected to an external resistor divider which senses the output voltage. The output of error amplifier is one of the two inputs of multiplier. A compensation loop is connected outside between INV and the error amplifier output. Normally, the compensation loop bandwidth is set very low to realize high power factor for PFC converter.

To make the over voltage protection fast, the internal OVP function is added. If the output over voltage happens, excess current will flow into the output pin of the error amplifier through the feedback compensation capacitor. (see Figure 11) The AP1661 monitors the current flowing into the error amplifier output pin. When the detected current is higher than 40μA, the

dynamic OVP is triggered. The IC will be disabled and the drive signal is stopped. If the output over voltage lasts so long that the output of error amplifier goes below 2.25V, static OVP will take place. Also the IC will be disabled until the output of error amplifier goes back to its linear region. R1 and R2 (see Fig. 11) will be selected as below:

$$\frac{R1}{R2} = \frac{Vo}{2.5V} - 1$$

$$R1 = \frac{\Delta V_{OVP}}{40\mu A}$$

Multiplier

The multiplier has two inputs. One (Pin 3) is the divided AC sinusoidal voltage which makes the current sense comparator threshold voltage vary from zero to peak value. The other input is the output of error amplifier (Pin 2). In this way, the input average current wave will be sinusoidal as well as reflects the load status. Accordingly a high power factor and good THD are achieved. The multiplier transfer character is designed to be linear over a wide dynamic range, namely, 0 V to 3V for Pin 3 and 2.0 V to 5.8 V for Pin 2. The relationship between the multiplier output and inputs is described as below equation.

$$V_{CS} = k \times (V_{COMP} - 2.5) \times V_{MULT}$$

where V_{CS} (Multiplier output) is the reference for the current sense, k is the multiplier gain, V_{COMP} is the voltage on pin 2 (error amplifier output) and V_{MULT} is the voltage on pin 3.

Current Sense/Current Sense Comparator

The PFC switch's turn-on current is sensed through an external resistor in series with the switch. When the sensed voltage exceeds the threshold voltage (the multiplier output), the current sense comparator will become low and the external MOSFET will be turned off. This insures a cycle-by-cycle current mode control operation. The maximum current sense reference is 1.8V. The max value usually happens at startup process or abnormal conditions such as short load.

POWER FACTOR CORRECTION CONTROLLER

AP1661

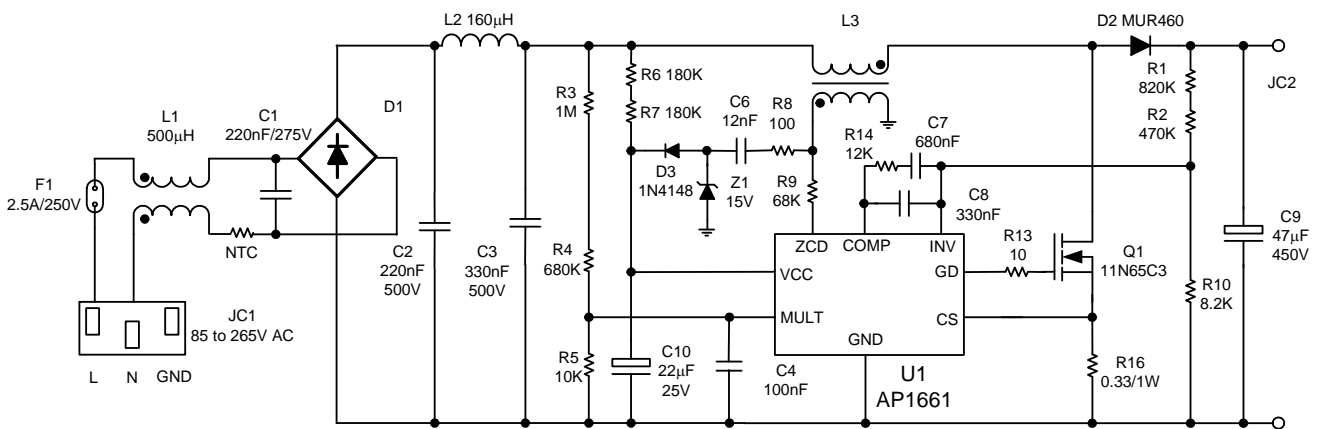

**Functional Block Description
(Continued)**

Zero Current Detection

AP1661 is a DCM boundary conduction current mode PFC controller. Usually, the zero current detection (ZCD) voltage signal comes from the auxiliary winding of the boost inductor. When the ZCD pin

voltage decreases below 1.6V, the gate drive signal becomes high to turn on the external MOSFET. 500mV of hysteresis is provided to avoid false triggering. The ZCD pin can be used for disabling the IC. Making its voltage below 0.15V or short to the ground will disable the device thus reduce the IC supply current consumption.

Typical Application

L3:
Core type RM10, material 3C90
primary: 660uH, 66 turns of litze wire 0.1mm*30
secondary: 7 turns wire of 0.2mm
