

# 16SCT100 1200V - 15A HIGH-SIDE SWITCH

16SCT100 - PRELIMINARY SPECIFICATION - REVISION OCTOBER 14, 2020

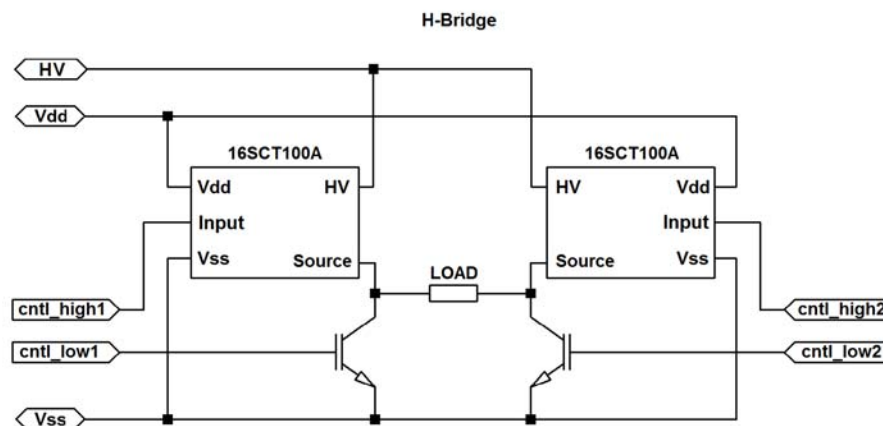

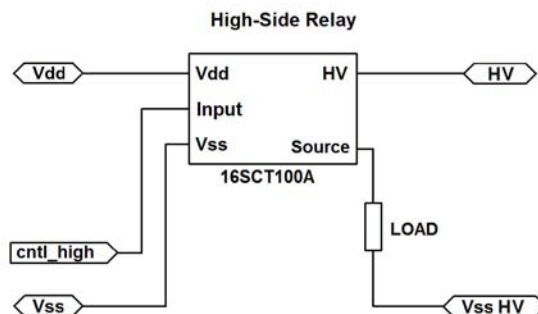

- Fully Integrated
- 1200V Blocking Voltage
- No External Components
- Fast Turn-Off Time
- CMOS Compatible Input
- Low  $R_{ds\ On}$
- Small TO263HV Package
- Low Energy Loss 140 $\mu$ W/A
- For Frequencies < 10kHz

## Description

The 16SCT100 is a 1200V 15A fully integrated high-side switch typically used in systems requiring H-bridges. The chip's integrated circuitry drives an integrated MOSFET gate above the HV supply to ensure that the transistor is adequately saturated. All control lines are low voltage. Package creepage distances allow for 1200V operation without the use of conformal coating or slots.

## Typical applications

# 16SCT100 1200V - 15A HIGH-SIDE SWITCH

16SCT100 - PRELIMINARY SPECIFICATION - REVISION OCTOBER 14, 2020

## Absolute maximum ratings

HV Power Supply (HV - Vss) . . . . .	1200 V
HV to Source Voltage (HV - Vs) . . . . .	1200 V
Negative Source Voltage . . . . .	-500 V
Continuous Source Current (25C) . . . . .	15A
Pulse Source Current (25C) . . . . .	19A
Vdd Power Supply (Vdd - Vss) . . . . .	18V
Operating Junction temperature . . . . .	-40 C to 150C
Storage temperature. . . . .	-65 C to 150C

## Recommended Maximum Operating Conditions

PARAMETER	MIN	MAX	UNIT
Operating voltage (HV - Vss)	40	1000	V
Operating voltage (HV - Source)	0	1000	V
Operating voltage (Vdd - Vss)	6	18	V

### Pin-out

**TO263**

**TO247**

### Marking

**TO263**

YY = Year  
WW = Week Number

**TO247**

## Pin Definitions

Pin #	SYMBOL	DESCRIPTION
1	Vss	Ground
2	Vdd	Low Voltage Supply
3	Input	Input signal (CMOS logic)
4	Source	Output fet source
5	HV	High Voltage Supply

# 16SCT100 1200V - 15A HIGH-SIDE SWITCH

16SCT100 - PRELIMINARY SPECIFICATION - REVISION OCTOBER 14, 2020

## Thermal Information

	SYMBOL	Thermal Metric	Value	Unit
1	$R_{\theta JA05}$	Junction-to-ambient thermal resistance double sided 0.5in <sup>2</sup> top-copper	50	C/W

### Application notes

The 16SCT100 package (TO-263HV) is a very effective solution for compact systems where saving space is a premium. Requiring no external component in most cases, its implementation is very straight forward. Like every integrated solution there are a few characteristics worth exploring in typical applications.

#### **Minimum Operating Voltage:**

This datasheet states the minimum operating voltage as 40V. This specification actually sells short the capability of the 16SCT100. 40V is the minimum voltage where starting a pulse is guaranteed. However once this pulse is started, the “on” condition will be retained down to voltages below 10V.

For example Figure 27 shows the 16SCT100 source voltage during the discharge of a 190uF capacitor charged with 300V through a 150 Ohm resistor on the source of the 16SCT100. We can see that the source voltage (current through the resistor) keeps flowing down to below 10V. It stops at about 120mSec on this chart.

Figure 28 shows more details of this behaviour on a pulse which is started with 40V on the same capacitor (red curve). We can clearly see that the capacitor discharges nicely down to below 10V (about 7V) before the 16SCT100 cannot keep the current flowing.

#### **Dealing with inductive Loads:**

The 16SCT100 was designed to drive resistive and inductive loads and some of its characteristics make it particularly interesting for driving inductive loads. In doing so the user needs to be careful about a few things.

If a negative voltage excursion is present on the source it should not go below the values shown in Figure 25. Doing so may irreversibly damage the chip. This being said the range of acceptable negative voltage excursion (several hundred volts) is substantial.

This negative excursion allowance make the 16SCT100 specially useful in driving inductive loads in discontinuous mode where the ringing following the load cut-off can be particularly challenging to manage. The user has simply to ensure that under worse -case scenario the ringing will not exceed the values in figure 25 and the system can be left to naturally settle if desired.

With HV at 400V driving an inductive resistor (see Figure 24) the negative source voltage excursion reaches about -300V. The 16SCT100 will tolerate this without damage, meaning that an anti-parallel diode (as used in Figure 26) is not necessary. Therefore this robustness to negative voltages make the 16SCT100 useful in driving inductive loads without additional anti-parallel diodes, provided the resulting ringing does not affect other parts of the circuit.

#### **Fast fall times at high voltages:**

The output FET of the 16SCT100 has a very fast fall time typically less than 100nSec for voltage drops of several hundred volts. This gives dV/dt of the order of 10,000V/uSec. Obviously this can impact neighboring parts of the circuit but also the chip itself.

To control this we have defined a Safe Operating Area (SOA) as per Figure 23 where below 800V any fall time is acceptable while at 1000V the fall time should be at least 200nSec. Violating these SOA limits may permanently damage the 16SCT100.

# 16SCT100

## 1200V - 15A HIGH-SIDE SWITCH

16SCT100 - PRELIMINARY SPECIFICATION - REVISION OCTOBER 14, 2020

---

To reduce the fall  $dV/dt$  the user can simply add a small capacitance in parallel with the load. Usually a few nF are sufficient to bring the  $dV/dt$  to a few 1000V/uSec. Since the 16SCT100 rise time is of this order of magnitude (about 0.4uSec) the application should be insensitive to this.

### **High Source Current Operation:**

The 16SCT100 will allow driving loads at up to 19A provided the junction temperature does not exceed 150C. Care should be taken to properly manage transient thermal conditions (Figure 22) and/or to properly heat sink the device while maintaining high-voltage isolation.

### **TO-263HV package (see Package Mechanical Information):**

This package allows up to 1200V isolation without using conformal coating and/or slots to meet UL 60950 (1200V clearance  $\geq 3.9\text{mm}$ ; creepage  $\geq 3.9\text{mm}$ ). The package offers pad-pin clearance of 7.17mm and creepage of 6.85mm, well in excess of the 3.9mm. The separation between the source pin and the input pin is 4.38mm minimum (e1 - b(max)), also well in excess of the 3.9mm requirement at 1200V.

### **Maximum operating frequency:**

The 16SCT100 has modest delays and rise time but has a fast fall time. This circuit is best suited for operation at frequencies below 10kHz. With delays to rise of about 500nSec and about the same for rise time it is very fast compared to an optically coupled high-side switch (mSec!) but about an order of magnitude slower than a typical low voltage high-side driver (~20-50nSec). The longest timing is the delay to fall time at about 1uSec. So this circuit turns on at 90% in about 1uSec and turns off to 10% in also about 1uS at  $V_{dd}=12\text{V}$ . This circuit is very well suited for acting as a high-side switch or high-side relay and can be used also in H-bridge configurations where the switching frequencies are below 10kHz.
