

## 5 channels step-up white LED driver

Datasheet – production data

### Features

- Operating input voltage range from 2.3 V to 5.5 V
- $\pm 7.5\%$  LED current accuracy
- Two LEDs in series per channel
- High side current source
- Up to 125 mA of total LED current
- 86% efficiency at 100 mA
- PWM dimming with automatic shutdown time window
- 2.5 MHz switching frequency
- CSP 12 bumps 0.4 mm. pitch 1.4 x 1.8 mm.

### Applications

- LCD backlight with up to 10 LEDs
- Cellular phones
- PDAs

### Description

The STLED25 is a fixed frequency, high efficiency, boost DC-DC converter with five parallel high side current sources. It is capable of providing 125 mA of total current with a maximum voltage of 7.5 V on each channel. Each current source supports single or dual LED connection. The output voltage of the step-up converter is automatically set at 100 mV above the highest voltage required on any driver, to guarantee proper operation of the linear current sources. The device implements a self-test feature to detect failure of any of the LEDs and to disable the related channel. The failure status is reset as soon the IC is disabled. This mode of failure detection allows the device to

continue operating driver channels that are functioning normally, while avoiding excessive power consumption or associated thermal issues. The control technique is able to maintain the efficiency close to 87% at medium load and higher than 85% at light or full load. The device also includes soft-start control, inrush current limit, thermal shutdown and inductor peak current limit. The STLED25 is packaged in a 12-bump CSP (1.4 x 1.8 mm, 0.5 mm height).

## 6 Detailed description

The STLED25 is a high efficiency white LED power supply which integrates a step-up converter and 5 high-side current sources. The device is controlled by two enable inputs called EN13 and EN45 according to the labels of the LED channels. EN13 enables LED channels 1, 2, 3 and EN45 enables LED channels 4, 5. The device is protected against shorted LED channels by short LED protection and against open LED channels by open LED protection. The device is able to recognize which channel has failed, and switch off this channel to maintain correct operation of the remaining channels. The STLED25 device is 125 mA total output current capable and works over a battery voltage range of 2.3 V to 5.5 V. The typical output voltage during operation corresponds to the voltage level equal to  $V_{FLED} + 125 \text{ mV}$ . The STLED25 device has an optimized switching power bridge to reach a high level of application efficiency (86%) with the typical battery voltage of 3.7 V. The device is also able to work at high efficiency when not all the LED channels of the device are used.

### 6.1 Boost DC-DC converter operation

The step-up bridge with current mode control of the regulation regulates the output voltage level according to the LED channel with the highest  $V_{FLED}$ , in order to maintain sufficient voltage headroom for the related current sources. The typical headroom of the current sources is in the range of 135 mV. The STLED25 contains a current limiter, with a typical value 600 mA, and soft-start control to limit the supply current from the battery. The method of regulation during startup and normal operation is explained in [Section 6.4](#).

### 6.2 Current setting

Each LED channel regulates to the same current. The value of the LED current is set by choosing the  $R_{SET}$  resistor. The current flowing through this resistor is mirrored in order to obtain the LED current. The multiplication factor is 390.

The LED current is calculated with the following formula:

#### Equation 1

$$I_{LED} = \frac{V_{SET}}{R_{SET}} \times 390$$

where:

$V_{SET} = 1.28 \text{ V}$  typical

### 6.3 EN13 and EN45

EN13 and EN45 play the dual role of enable pin and PWM dimming. EN13 drives strings D1, D2, D3 while EN45 drives D4 and D5. Both EN13 and EN45 are pulled down internally by 100 k resistors.

The EN pins accept a signal between 100 Hz and 800 Hz, at duty cycles from 0.39% to 100%. The output average current maximum error is 10% at 0.39%, PWM duty cycle at 300 Hz.

## 6.4 Modes of operation

### Shutdown mode

The device is in shutdown with minimum current consumption. It goes to PWM\_start as soon as EN13 or EN45 are pulled high.

### PWM\_start

Once EN<sub>xx</sub> is asserted, the DC-DC is turned ON with a soft-start procedure until V<sub>OUT</sub> reaches 7 V; this phase takes around 1.2 ms.

If EN<sub>xx</sub> remains asserted, the device will stay in this condition and wait for 10 ms (PWM\_start\_up), then the STLED25 goes to PWM\_normal mode. If the next EN is asserted during the PWM\_start\_up mode, the device will immediately enable the LED current sources and continue in PWM\_normal mode.

### PWM\_normal

In this mode of operation the drivers are in the ON state delivering current to the LEDs, and the DC-DC converter maintains the V<sub>OUT</sub> value with enough headroom to keep the high side current sources in regulation.

When both EN pins are low, the drivers are turned off and the RUN\_HOLD timer starts.

### RUN\_hold

The RUN\_hold time lasts approximately 30 ms. During this time, the DC-DC converter maintains the last optimum voltage on V<sub>OUT</sub>. If RUN\_hold time elapses without EN reassertion, then the STLED25 goes into shutdown mode. If EN is reasserted, the device goes to PWM\_normal mode.

Figure 19. Modes of operation

## 6.5 Undervoltage lockout

The undervoltage lockout function prevents improper operation of the STLED25 when the input voltage is not high enough. When the input voltage is below the UVLO threshold, the device is in shutdown mode. The hysteresis of 100 mV prevents unstable operation when the input voltage is close to the UVLO threshold.

## 6.6 Overtemperature protection

An internal temperature sensor continuously monitors the IC junction temperature. If the IC temperature exceeds 150 °C (typical), the device stops operating. As soon as the temperature falls below 135 °C (typical), normal operation is restored.

## 6.7 Open LED protection

The device is able to detect an “Open LED” failure in each LED channel independently. When this failure appears, the DC-DC increases the output voltage to maintain the current source headroom voltage until the OVP threshold is reached; the device detects which LED channel is the root cause and switches off this LED channel. This state is maintained until the STLED25 goes into shutdown mode.

## 6.8 Overvoltage protection

The device has overvoltage protection on the  $V_{OUT}$  pin to protect the device and external components against the high voltage coming from the DC-DC, in case of a disconnected load. When the output voltage level reaches the OVP threshold (9.3 V typical), the DC-DC is turned off until the output voltage level goes below the OVP threshold. The hysteresis of the OVP threshold is approximately 250 mV.

## 6.9 Short LED protection

The device is able to detect a shorted LED in each LED channel independently; when the protection detects a failure on any of the LED channels, it switches off this channel until the STLED25 enters shutdown mode.

## 7 Application information

### 7.1 External passive components

#### 7.1.1 Inductor selection

The inductor is the key passive component for switching converters.

For the STLED25, an inductance of 4.7  $\mu\text{H}$  is recommended. It is very important to select the right inductor according to the maximum current the inductor can handle to avoid saturation. The peak current for the step-up can be calculated with the following formula:

##### Equation 2

$$I_{\text{PEAK-BOOST}} = \frac{V_{\text{OUT}} \times I_{\text{OUT}}}{\eta \times V_{\text{IN MIN}}} + \frac{V_{\text{IN MIN}} \times (V_{\text{OUT}} - V_{\text{IN MIN}})}{2 \times V_{\text{OUT}} \times f_s \times L}$$

where:

$V_{\text{OUT}}$ : step-up output voltage. The boost control loop keeps it 135 mV higher than the maximum among VD1-D5

$I_{\text{OUT}}$ : total output current

$V_{\text{IN}}$ : input voltage of STLED25

$f_s$ : switching frequency. Use the minimum value of 2.25 MHz for the worst case

$\eta$ : efficiency of step-up converter. It is 0.87 at 75 mA load

**Table 7. List of recommended inductors**

Manufacturer	Part number	Inductance [ $\mu\text{H}$ ]	Saturation current [A]	Size [mm]
Samsung	CIG21K4R7SCE	4.7	0.6	0805
Murata	LQM21PN4R7	4.7	0.6	0805

#### 7.1.2 Input and output capacitor selection

It is recommended to use ceramic capacitors with low ESR as input and output capacitors in order to filter any disturbance present in the input line and to maintain stable operation of the step-up converter. A minimum real capacitance value of 1  $\mu\text{F}$  must be guaranteed for  $C_{\text{IN}}$  and 4.2  $\mu\text{F}$   $C_{\text{OUT}}$  in all conditions.

Table 8. Input and output capacitor

Manufacturer	Part number	Nominal capacitance [ $\mu\text{F}$ ]	Rated voltage [V]	TCC	Size [mm]
<b>C<sub>IN</sub></b>					
Murata	GRM155R60J155M	1.5	6.3		0402

<b>C<sub>OUT</sub></b>					
Murata	GRM219R61A106ME47	10	10		0805

## 7.2 Recommended PCB layout

The STLED25 is a high-frequency power switching device, so it requires a proper PCB layout in order to obtain the necessary stability and optimize line/load regulation and output voltage ripple. Input and output capacitors must be as close as possible to their relative pins.
